## introduction

As an important part of this 6th edition of the Westinghouse manual of outdoor bushings, full data on the ASA (American Standards Association) development is included. The outstanding service record of Westinghouse bushings has contributed strongly to improved operating safety, greater service continuity and unmatched reliability. Industry recognition of this design has led to the ASA Standards for equipment voltages 23 kv to 196 kv. The Westinghouse bushing design required very little modification to meet the ASA Standards.

Also outlined are the basic design principles of Westinghouse bushings that are so well represented in the ASA Standards, as well as some of the outstanding design developments represented in over 50 years of Westinghouse bushing experience.

Part 1 presents a tabulation of the Westinghouse standard bushings in voltages from 15 kv to 345 kv.

Parts 2, 3, 4, and 5 present discussions and illustrations on earlier designs of Westinghouse power circuit breaker and transformer bushings, along with detailed engineering data concerning their interchangeability, tests, maintenance, repair and storage. The general index, at right, will assist in locating specifically the various phases of discussion and data.

## development program and basic design

### over 50 years of Westinghouse condenser bushing experience

The development program for Westinghouse Outdoor Bushings has continued aggressively since 1907. Improvements in impulse and power factor testing equipment, together with many field tests, have resulted in condenser bushings which place Westinghouse in a leading position on high voltage apparatus.

The basic principle of Westinghouse condenser bushing design, as originated by Westinghouse in 1907, is now the standard for the industry. Proved through the years, this design adds substantially to the reliability of circuit breakers and transformers. Research and engineering studies are constantly being made to improve materials, details of construction and manufacturing processes.

### specific phases of Westinghouse condenser bushing development and improvement since 1907

#### 1. design established

Prior to 1907, Westinghouse used bulk type non-condenser bushings for ratings 15 kv and above. In 1907, Westinghouse adopted the principle of bushing design wherein the stress distribution through the wall and over the surface is controllable and made uniform by subdividing the insulation into many condensers in series. The first outdoor condenser bushings were made in 1909 for 44, 66, and 100 kv, and some of these bushings are still in service. Thousands of bushings of all voltage classes have been manufactured in the succeeding years. Very little service trouble has been experienced, and such difficulties as have occurred did not involve the basic condenser principle.

#### 2. construction

In 1920 to 1922, important improvements were made in the material used in the condenser itself and in the weather casing construction.

#### 3. filling

At the same time (1920-22), a more fluid type of filling plastic replaced the hard gum.

#### 4. finish

A new varnish for finishing the condenser itself was introduced in 1938 with better moisture resistance and higher resistance to tracking under dielectric stress.

#### 5. gaskets with spring compression

In 1934 a sealing and stop gasket design was developed, with spring compression, to maintain continuous pressure on the gaskets under all conditions.

#### 6. porcelain

In 1922, the single piece porcelain was developed for 33 and 44 kv bushings . . . in 1925, for 66 kv bushings . . . and in 1928-29 for the higher voltage classes.

#### 7. solder-sealed

In 1940, experimental type "S" solder-sealed designs for voltages up to and including 69 kv were made and tested, and a few bushings of this type placed in service. This is now standard for voltage classes 15 to 69 kv, inclusive.

In 1940, the type "N" and "ON" bushings were developed for ratings of 92 to 288 kv, inclusive, permitting a common design, except for a few parts, for plastic-encased and oil-encased bushings for circuit breakers and transformers.

#### 8. oil-impregnated condenser

In the latter part of 1942, a new oil-encased bushing with oil-impregnated paper condenser—the type "O"—was placed in production for voltages 92 to 288 kv. This superseded the types "N" and "ON" designs.

#### 9. Micarta® improvements

There has been continuous improvement in the Micarta used in winding condenser bushings.

## Westinghouse modern bushing design

**the principle:** Condenser construction provides uniform voltage stress throughout insulation radially and over surface of bushing longitudinally.

**the design:** A series of equal capacity condensers, spaced concentrically around the conductor, consists of alternate layers of aluminum foil and impregnated paper. Extremely thin, specially-treated foil improves adhesion and electrical coordination. Continuous winding under carefully controlled conditions eliminates voids and variations in resistivity. Impregnation of supercalendered paper imparts unexcelled dielectric strength. Type "S" bushing resistance to moisture and tracking under dielectric stress is provided by baked varnish finish. Type "O" bushings are porcelain-enclosed and the condenser vacuum oil-impregnated.

**the advantages:** Smooth voltage gradient throughout bushing eliminates internal corona, radio and TV interference, and prevents insulation breakdown. Condenser principle design is the most efficient ever developed.

## type "O"

for transformers and circuit breakers

### general description

The type "O" condenser bushings have an oil impregnated kraft paper condenser inside an oil filled chamber. The chamber consists of a cap, an upper porcelain weather casing, a metal mounting flange, a lower porcelain and a lower porcelain support. All parts are held under pressure from springs in the cap. Joints to the porcelain are sealed with cork neoprene gaskets encircled by neoprene asbestos stop gaskets. Ample expansion space is allowed in the cap to keep the pressure changes due to thermal expansion to a small amount.

### recommendations for maintenance and repair: see I L 33-354-1

Make visual inspection as received and twice a year thereafter. Inspect for physical damage, leaks, and bad connections. The bushings should be cleaned at intervals to keep the insulation surfaces free from accumulation of foreign materials. Paint exposed metal to protect from the weather.

Oil level in bushing is shown by gauge on side of cap. Any bushing showing decreasing oil level should be investigated for leaks, and repaired. Small amounts of oil can be added to bushing through the flange sampling valve with a special tool.

**caution:** Do not break any of the oil seals or drain oil for test unless power factor or capacitance tests or some other reason indicate the need for investigation.

Where power factor testing schedules have been adopted make power factor and capacitance test the first year and recheck every second year. For limit of power factor with both ends of bushing clean and dry, see part 3, page 27.

For any major repairs, it is recommended that the damaged bushings be returned to the factory where special equipment is available for drying and oil impregnation.

Specify the voltage rating, S.O. and serial number from bushing nameplate and the S.O. of apparatus when ordering spares or replacements.

For replacements see part 5.

### general note

Due to the necessarily increased diameter of lower ends on type "O" bushings as compared to other types used on transformers where no porcelain covering was used over this end, it is necessary that each application as a replacement for older transformer bushings be checked for possible interference with insulating barriers. Transformers manufactured since 1944 have a clearance suitable for the type "O" bushing.

for power circuit breakers  
and transformers

page 13

## type "S"

for transformers and circuit breakers

### general description

Bushings of this type are hermetically sealed with all joints sealed by brazing or soldering. No cement and no gaskets are used in the construction. The top cap, the ring on lower end of porcelain and the porcelain support are all of spun or drawn copper, making it impossible to have heavy strains on the porcelain. The flange with parts brazed together is of pressed-on type. A platinum film is fired into the glaze of the porcelain to which the flexible spinnings at each end are soldered. All openings for filling or for air escape during filling are also solder sealed. Ample expansion space is allowed in the cap to keep the pressure changes due to thermal expansion to a small amount.

Type "OS" has been used to designate oil encased bushings of this construction. A few designs of oil encased solder seal bushings with a modified cap construction are designated type "OS1".

### recommendations for maintenance and repair

See IL 33-354-2.

Make a visual inspection as received and twice a year thereafter.

Where power factor testing schedules have been adopted make power factor and capacitance tests the first year.

Recheck with power factor test set annually, any bushings that have noticeably higher power factor than the average power factor for the bushings of this type.

Recheck every two years with the power factor test those bushings that are consistently under the safe power factor limits as indicated by the curve on page 27 of this manual.

Damaged bushings should be rebuilt as duplicates of the original bushings, but first the condenser elements should be rechecked with the power factor test, and if the power factor is above 2% at 25°C, they should be dried out according to instructions contained on page 31. At the same time that the power factor check is made, a capacitance check should be made. A condenser element can be safely rebuilt if the capacitance of the bushing does not exceed by more than 10% the average for bushings of the same ratings. A bushing that has been rebuilt, should be given a power factor test as well as the standard 60 cycle voltage test, before being returned to service.

Spares or replacements will be ASA Standard bushings where possible.

Specify the voltage rating, stock order and serial number where available, when ordering spares or replacements.

### oil circuit breaker bushing with solid stud

### transformer bushing with draw-through cable

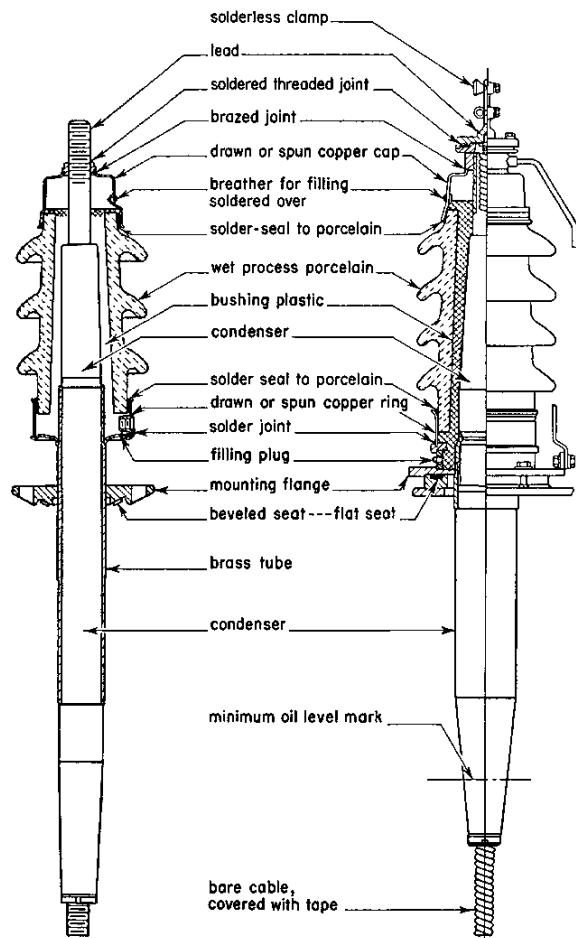

figure 12: Typical construction of type "S" bushing manufactured 1941 to date for 15 kv to 69 kv (inclusive).

**part 2****section a: modern standard bushings****type "RJ"**

for transformers

**general description**

"RJ" bulk type bushings are used only for voltages 15 kv and below. This bushing is made up of a single piece wet process porcelain with a flange sleeve rolled into grooves in the porcelain over silastic gaskets. A flange plate for clamping the bushing to the boss is made captive by this rolling and becomes an integral part of the porcelain assembly. Three types of leads are used in these bushings: a solid stud which goes through the cap, a solid stud which screws into the cap and a hollow tube with a cable conductor inside of it. For the low voltage class (5 kv) the leads are centered within the porcelains with cotton tape. For higher voltages the leads are centered within the porcelain by a Micarta tube.

Bushings like this have been used on transformers since 1955.

**recommendations for maintenance and repair**

Inspect periodically for broken or cracked porcelains and faulty gaskets. Power factor tests need not be made, as such tests will not show defects in the bushing. Repairs to damaged bushings may be made preferably at the factory. Porcelains and other parts are carried in stock to give prompt service.

**recommendations for spares**

Spares or replacements will usually be duplicates of the original design. In some cases a later style of porcelain will be furnished which will be interchangeable and will fit the original cover mounting of the apparatus.

When ordering spares or replacements, specify the voltage rating of the bushing, or transformer, and the shop order or serial number of the apparatus along with all information given on the bushing nameplate.

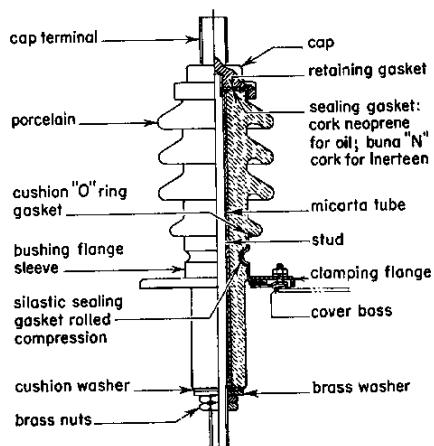

figure 13: Typical construction of type "RJ" bushing manufactured from 1955 for 15 kv and below.

**type "J-2"**

for transformers

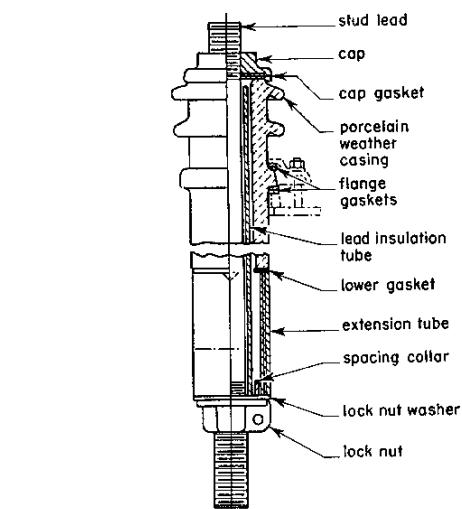

figure 14: Typical construction of type "J-2" bushing manufactured from 1922 for 4.3 to 23 kv (inclusive).

**general description**

This is a single piece porcelain tube, bulk type bushing, with solid stud lead through the tube. The porcelain is cast with a collar below the rain sheds; this collar fits over the gasketed mounting of the transformer cover.

From 1922 to 1955, bushings of this type have been used for circuits of 4.3 through 23 kv.

**recommendations for maintenance and repair**

Inspect periodically for broken or cracked porcelains, and faulty gaskets. Power factor tests need not be made, as such tests will not show defects in the bushing.

Repairs to damaged bushings may be made preferably at the factory. Porcelains and other parts are carried in stock to give prompt service.

**recommendations for spares**

Spares or replacements will usually be duplicates of the original design. In some cases a later style of porcelain will be furnished which will be interchangeable and will fit the original cover mounting of the apparatus.

When ordering spares or replacements, specify the voltage rating of the bushing, or transformer, and the shop order or serial number of the apparatus.

## part 2

### section b: bushings manufactured from 1934 to 1942

#### type "G"

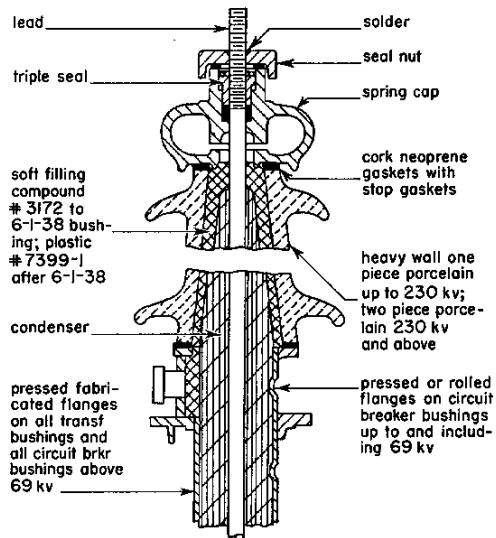

figure 15: Typical construction of type "G" bushing manufactured 1934 to 1942 for 15 to 288 kv (inclusive).

For maintenance and repairs, see part 3.

For replacements, see part 5.

#### general description

Bushings of this type have one-piece porcelain weather casings on all voltage ratings below 288 kv. On voltage ratings 288 kv and above, two-piece porcelain weather casings are generally used. In all voltage ratings, the porcelains are end clamped between the cap and the mounting flange. The mounting flanges are pressed on to the condenser elements for all transformer bushings and for all circuit breaker bushings above 69 kv. Circuit breaker bushings rated 69 kv and below, have the mounting flanges secured to the condenser element by pressing or by rolling the flange into grooves previously machined into the condenser element at one or more places. A globular shaped spring cap designed to maintain pressure on all gaskets is used. A triple seal stuffing box is constructed in the cap. Soft filling compound #3172 to June, 1938 and plastic #7399-1 after June, 1938, cork gaskets prior April, 1935 and cork-neoprene gaskets after April, 1935 are used in bushings of this type.

**type "OG"** bushings are oil encased, and have the weather casing filled with oil instead of plastic. There is a sump and sampling valve at the flange for testing or draining the oil.

**type "IG"** bushings have the weather casing filled with Inerteen instead of plastic, and are provided with a sump and sampling valve at the flange.

**types "GI", "OGI", and "IGI"** bushings are the same as described above, but are designed for use in Inerteen filled apparatus. Condenser bushings designed for Inerteen filled apparatus may be used in oil filled apparatus, but *bushings for oil filled apparatus must not be used in Inerteen*. The Micarta and varnish of standard condenser bushings will not withstand operation in Inerteen.

#### type "G-1"

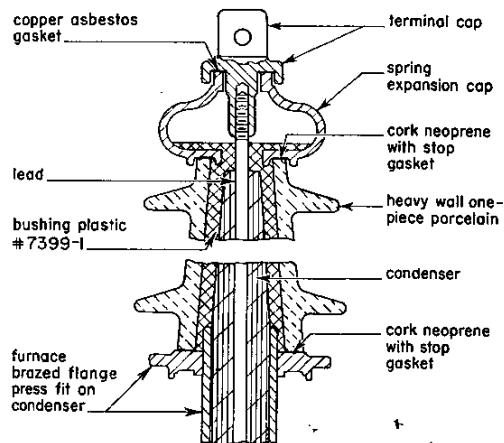

figure 16: Typical construction of type "G-1" bushing manufactured 1937 to 1942 for 15 to 23 kv (inclusive).

Type "G-1" is same as "G" except for cap construction as shown.

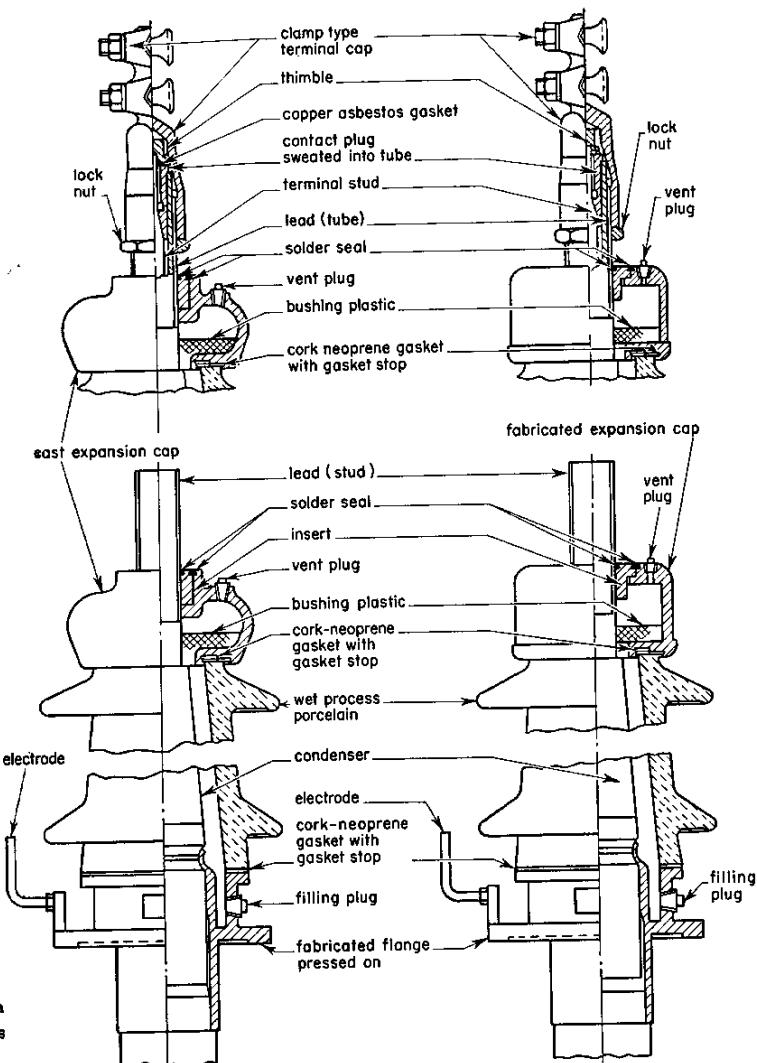

Maintenance and repairs same as type "G".

Spares or replacements will generally be type "S" bushing, see part 5.

**part 2** section b: bushings manufactured from 1934 to 1942

**types "G<sub>1</sub>" and "G<sub>2</sub>"**  
for transformers only

**figure 17:** Typical construction  
of types "G<sub>1</sub>" and "G<sub>2</sub>" bushings  
for 15 to 46 kv (inclusive).

**general description**

Bushings of these types are modifications of type "G" bushings. They were designed when aluminum became unobtainable for spring caps, which were used on type "G" bushings. With the exception of the cap, all other parts of these bushings are identical with those of type "G" bushings. For type "G<sub>1</sub>" the globular shaped cap is cast from bronze alloy. For type "G<sub>2</sub>" the cap is fabricated from brass parts brazed together. In both cases the caps have special machining for extra thick cork-neoprene gasket, which takes care of difference in expansions of copper lead and porcelain weather casing. Both these constructions are limited by the lengths of the condenser leads and therefore were not used for bushings above 46 kv class.

In assembly the bushing is compressed in the press and the insert is screwed into the recess with an air motor. After pressure is

released the insert is soldered to the cap and to the lead simultaneously and forms an air-tight joint. Plastic #7399-1 is used for filling the space between condenser and porcelain.

Types "OG<sub>1</sub>" and "OG<sub>2</sub>" bushings are identical in construction with types "G<sub>1</sub>" and "G<sub>2</sub>", but have the space between condenser and porcelain filled with oil instead of plastic. Their flanges have sumps and sampling valves for testing and draining the oil.

Types "G<sub>1</sub>-I" and "OG<sub>1</sub>-I" bushings are identical with those described in paragraphs above but are designed for use in Internen filled apparatus. Bushings of these types may also be used on oil-filled apparatus.

For maintenance and repair, see part 3.

For replacements, see part 5.

and transformers

page 17

## type "K"

for transformers principally

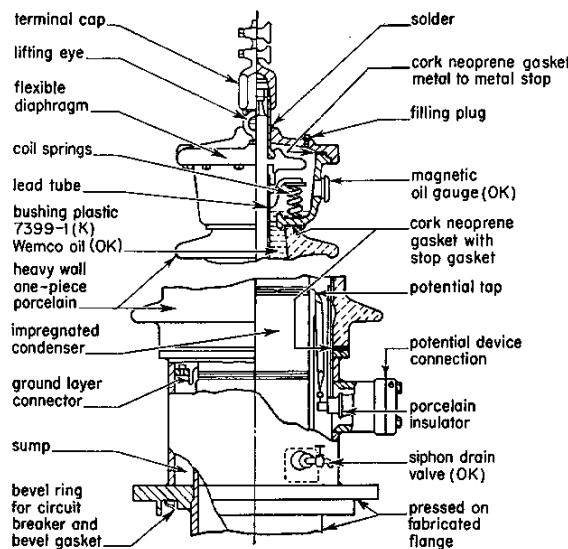

figure 18: Typical construction of type "K" bushing manufactured 1937 to 1941 for 34.5 to 230 kv (inclusive).

## general description

This type of bushing is either oil or plastic encased. It is recognized by a cast cap, with bolted cover, one-piece porcelain with gaskets at the ends under constant pressure of internal steel springs inside the cap. The higher voltage ratings (69 kv and above) are the principal ones built with the type "K" construction.

**type "OK"** has been used to designate oil encased bushings having this construction. The oil encased design has a sampling valve and oil sump at the bushing flange. A magnetic oil gauge is mounted on the side of the cap. This oil gauge has been supplied with all type "OK" bushings for 92 kv and above, and for some of the 69 kv bushings.

In both types "K" (plastic encased) and "OK" (oil encased) the construction is identical except for the addition of a magnetic oil gauge on the cap and a sampling valve at the flange for the type "OK". Provision for expansion and contraction of the lead is obtained by a flexible diaphragm inside the cap, as shown in the sketch. When the bushing is used on heavy current circuit breakers, a central cable lead is provided, which shunts part of the current from the flexible diaphragm.

**type "OKI"** bushing, having this same construction, has an oil filled weather casing. The bushing is designed for use in Inerteen-filled apparatus.

## recommendations for maintenance

Make a visual inspection twice a year. See page 28 of this manual. Where power factor testing schedules have been adopted make power factor and capacitance tests the first year.

Test sample of oil the first year on oil encased bushings. If the bushing does not have a magnetic oil gauge, check the liquid level by removing the test plug in the top of the cap.

Recheck the oil every year on any bushings that are noticeably higher in power factor than the average power factor for the bushings of this type.

Recheck every two years with the power factor test those bushings which are consistently well under the safe power factor limits as indicated by the curve on page 27 of this manual.

Damaged bushings should be rebuilt in duplicate of the original bushings, but first the condenser elements should be checked for power factor. If the power factor is above 2% at 25°C, they should be dried out according to instructions on page 31. A capacitance check should be made at the same time as the power factor is measured. A condenser can be safely rebuilt if the capacitance of the bushing is not more than 10% above the average for bushing of the same design. A bushing that has been rebuilt should be given a power factor and capacitance test as well as the standard 60 cycle withstand test before being returned to service.

If the magnetic oil gauge is damaged, the dial mechanism may be removed from the bushing cap for repair or replacement. It is not necessary to open the cap or break any gasket seal to remove the dial mechanism of the gauge. The motion of the float inside the cap is transmitted through the cap casting magnetically without piercing the cap. Damaged dials should be returned to the factory (Sharon) for repair or replacement.

## recommendations for spares

Spares or replacements will be type "N" or "OK<sub>1</sub>" or "O" bushings for 92 kv and above, and type "OK<sub>1</sub>" or "S", for 69 kv and below. The replacement bushings will have the same key number and will be interchangeable without adapters.

Specify the voltage rating, stock order, and serial number of the apparatus when ordering spares or replacements.

**part 2** section b: bushings manufactured from 1934 to 1942  
**types "K<sub>1</sub>" and "OK<sub>1</sub>"**  
for transformers only

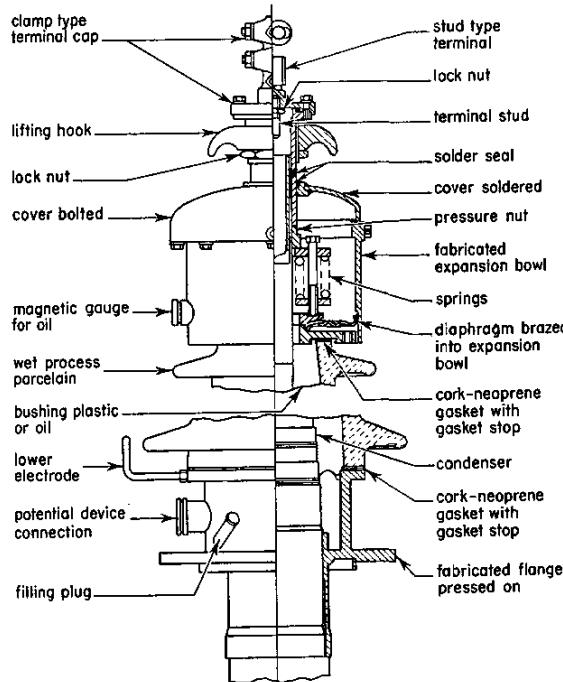

figure 19: Typical construction of type "K-1" bushing manufactured from 1939 to 1942 for 34.5 kv and above.

#### general description

Bushings of this type are modifications of type "K" bushings and cover the same range; that is, from 34.5 kv and up. These bushings are used in all cases when special requirements of the customer cannot be met with standard type "S", type "N" or type "O" bushings. For example, when customer requires oil-filled bushings of 69 kv or below equipped with magnetic oil gauges.

With the exception of the cap design, construction of other parts is similar or identical with bushings of other types. Thus bushings of 69 kv class and below have their condensers, flanges and weather casings identical with those of type "G" bushings. Bushings of 92 kv class and above have other parts identical with those of type "N" bushings.

Types "K<sub>1</sub>" and "OK<sub>1</sub>" bushings have fabricated caps and the cover is either bolted or soldered to the expansion bowl. A single disc diaphragm is brazed to the bowl inside of it and the condenser lead is brought through the cover.

The space between condenser and the weather casing is filled with plastic #7399-1 for type "K<sub>1</sub>" and with oil, for type "OK<sub>1</sub>". The oil-filled type "OK<sub>1</sub>" bushings have magnetic oil gauges for indicating oil level.

For maintenance and repair, see part 3.

For replacement, see part 5.

**type "M"**  
for circuit breakers only

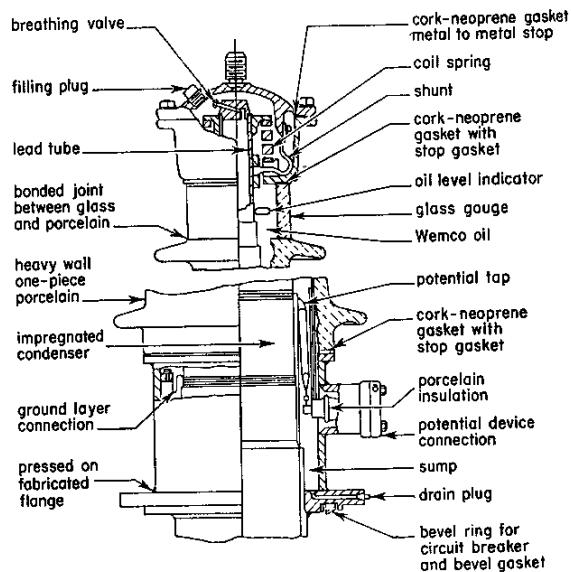

figure 20: Typical construction of type "M" bushing manufactured from 1937 to 1941 for 46 to 230 kv (inclusive).

#### general description

Bushings are of oil encased type with one-piece porcelain sealed by a gasket to a gauge glass which has great resistance to actinic rays. The cap is bolted over a cork-neoprene gasket with metal-to-metal stop. An internal spring maintains a definite pressure on other joints. The current is by-passed around this spring by means of shunts to prevent magnetic heating of springs. Cork-neoprene gaskets with asbestos neoprene gasket stops are used at ends of the weather casing. The cap is hermetically sealed, but when tubing conductor is used, the tubing is used to provide additional expansion space. The cap is sealed from the tube for shipment with a screw valve, which can be operated through the filling hole in the cap. The normal height of oil at 25°C is in the middle of the gauge glass. A sump and sampling connection are supplied at the flange.

For maintenance and repair, see part 3.

For replacements, see part 5.

page 19

## type "N"

for transformers and circuit breakers

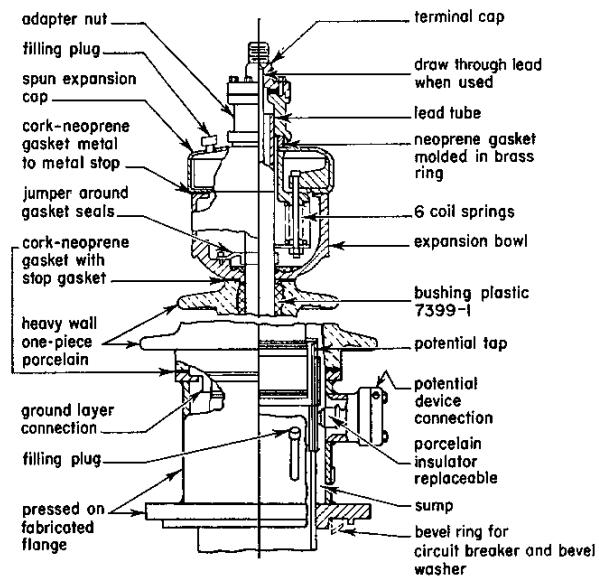

figure 21: Typical construction of type "N" bushing manufactured 1940 through 1942 for 92 to 228 kv (inclusive).

## general description

Bushings of this type have a spun or drawn type cap section with multiple coil springs for placing definite pressure on all gasketed joints. The gaskets at ends of the porcelain and at ends of gauge glass in the oil encased "ON" type are of cork-neoprene with asbestos neoprene gasket stops. On the plastic encased type 'N', the gasket between bowl and spun section is of cork-neoprene with a metal to metal stop. The gasket between stud, terminal adapter and spun section is a three way seal of neoprene completely enclosed by metal in an unique fashion. The oil encased "ON" has a gauge glass and gauge glass support to replace the cast metal bowl of the plastic encased "N" and also has a sampling valve at flange. Otherwise the "N" and "ON" bushings are alike. The construction except for the draw-through lead for transformers is the same for circuit breakers and for transformers. Porcelains are of one piece type except for the 288 kv where 2 pieces are used. The gauge glass for the "ON" almost entirely diverts the actinic rays. Flanges are of structural type pressed on to the condenser.

For maintenance and repair, see part 3.

For replacements, see part 5.

## types "A", "B", "C", "D", "E" and "F" recommendations for maintenance

The insulation in the types "A", "B", "C", "D", "E", or "F" bushing condenser does not have the dielectric strength we have been able to build into bushings made more recently. The mechanical construction of the weather casing and cap is not considered good enough to exclude the possibility of water entering the bushing and contributing to an electrical breakdown of the insulation. For these reasons, we believe these bushings are incapable of maintaining the interruption free service that is expected on modern transmission and distribution circuits. It is therefore recommended that these bushings be replaced with bushings of modern design.

Until replacements can be made, the bushings should be given a visual inspection twice a year. The inspector should watch for broken porcelains, defective gaskets, and evidence of leaking compound. If any bushings are found with these defects, the bushings should be replaced with a modern bushing.

Where power factor testing schedules have been adopted, the power factor and capacitance should be checked annually and compared with previous measurements to observe if there is any evidence of water getting into the bushing. If the capacitance is more than 15% higher than the average capacitance of like bushings, or if the power factor is higher than the curve of acceptable power factor limits, fig. 32, page 27, or shows an appreciable increase over the past measurements, the suitability of the bushing for continued service is doubtful. In such a case, it should be replaced as soon as possible with the bushing recommended for this purpose in the engineering recommendations for outdoor circuit breaker and transformer bushings, pages 46 to 83, inclusive.

## recommendations for spares and replacements

For spares and replacements an up-to-date bushing is recommended. Wherever the design of the apparatus permits, the replacement will be in accordance with the engineering recommendations for outdoor circuit breaker and transformer bushings on pages 46 to 83. In some cases, it may not be possible to provide a completely impulse coordinated design as it will generally be necessary to maintain lengths on the inside of the apparatus and sometimes necessary to maintain the original diameter to fit the holes in apparatus covers or to fit bushing type current transformers. Wherever possible, present standards will be used.

Where drawings for replacement bushings have not been made, we will make them, and where an adapter is required, we will provide the adapter, and its price will be included in the price of the bushing.

When ordering bushings for spares or replacements, specify the voltage rating, shop order and serial number, where available, and if possible provide also the shop order of the circuit breaker or transformer in which the bushing is to be used.

## types "H-1"—"H-2"

for transformers only

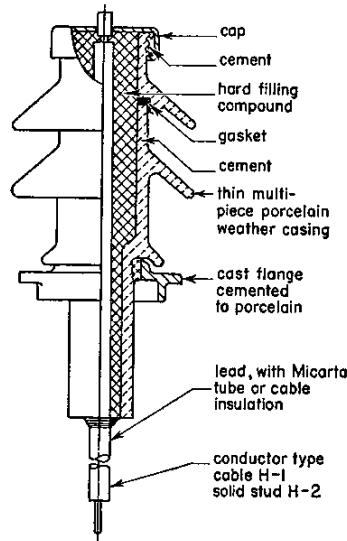

figure 28: Typical construction of types "H-1" and "H-2" bushings manufactured from 1909 to 1922 for 13.8 kv to 44 kv (inclusive).

## general description

"H-1" and "H-2" bulk type porcelain tube bushings were used on voltages up to 44 kv. For 22, 33 and 44 kv multi-piece porcelains were used, cemented together with felt or cork gaskets between sections. The flange was cemented onto the lower porcelain tube.

For "H-1" the conductor through the tube consisted of a solid stud, surrounded by a Micarta tube.

For "H-2" the inside of the porcelains was filled with a hard setting gum.

## recommendations for maintenance

Where power factor testing schedules are adopted make power factor tests annually, inspect visually twice a year. Replace with bushings of modern design, any bushings found defective either by the power factor test or by inspection.

## recommendations for repair

We do not recommend a repair on this type of bushing, because:  
(a) The quality and quantity of the insulating material is much less than present standards, (b) the metal parts are not adaptable to assembly with the insulating elements of later design bushings, and (c) the cost of parts plus the cost of dismantling and rebuilding does not warrant making replacements with parts of the old design.

See page 22 for spares and replacement

**part 2****section c: bushings manufactured from 1909 to 1933****types "H-1"—"H-2" continued****recommendations for spares**

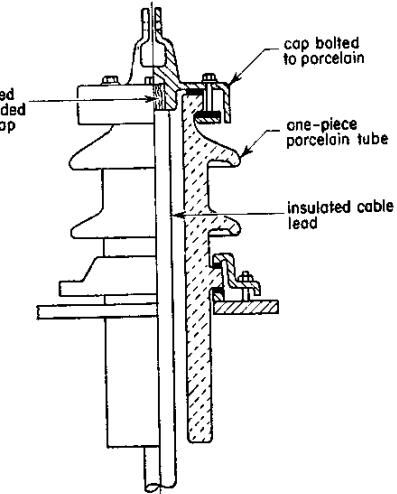

Bushings of this type were built before standards for impulse coordination were established and at a time when many of the modern testing facilities were not available. Since then, important advances have been made in design, materials, and processes, the benefits of which have been incorporated in modern bushings. It is not always possible to provide interchangeable bushings of modern design completely impulse coordinated because it is generally necessary to maintain lengths and diameters the same as the old bushing. However, the advantages of increased insulation strength through the bushing materials, together with improved weatherproofing and the reduction in future maintenance, warrants replacing these bushings with new ones of modern design. Wherever possible, present standards will be used in the design and construction of bushings intended for spares, or as replacements for bushings of this class.

In order to keep to a minimum the number of designs, and thus the number of spare bushings that the operator must carry in stock we use, wherever possible, a standard up-to-date bushing in filling an order for spares. In some cases we fit it to the apparatus by means of adapters, rather than supply new designs for each of these old bushings.

Wherever such a bushing or bushing and adapter has been designed it is indicated in the tabulation of drawings, pages 46 to 83. In each case the drawing number of the adapter is given, or if required, but not already made, it is so indicated by the ③. When such a design has not been made, we will make it with no development cost to the customer. The cost to the customer of the bushing and adapter will be the same as if the old design had been duplicated.

**recommendations for replacement**

These bushings are from 25 to 35 years old. On account of their age, and the improvements which have been made since they were manufactured, it is recommended that type "H-2" bushings be replaced with bushings of modern design.

**type "J-1" for transformers only**

**figure 29: Typical construction of type "J-1" bushing manufactured from 1922 to 1930 for 4.3 kv to 23 kv (inclusive).**

**general description**

This is a single piece porcelain tube bulk type bushing, with heavily insulated cable lead passing through the bushing. The porcelain is cast with a collar below the rain sheds; this collar fits over the gasketed mounting ring of the transformer cover.

The bushings were used from 1922 to 1930, on circuits for 23 kv and below. A number of "J-1" bushing designs have been made since 1938 in which the lead is surrounded by a copper tube clamped to the ends of the porcelain similar to the "J-2" design. (See page 14.)

**recommendations for maintenance and repair**

Inspect periodically for broken or cracked porcelains and faulty gaskets. Power factor tests need not be made, as such tests will not show defects in the bushing.

Repairs to damaged porcelains or cables may be made, preferably at the factory (Sharon). Porcelains and other parts are carried in stock so that such repairs can be made promptly.

These cable type bushings must be handled carefully to prevent breaking the insulation on the cable.

**recommendations for spares and replacements**

Spares or replacements will usually be duplicates of the original design. In some cases a later style of porcelain will be furnished which will be interchangeable and will fit the original cover mounting of the apparatus.

When ordering spares or replacements, specify the voltage rating of the bushing or transformer winding, and the shop order or serial number of the transformer.

Spare bushings with cable leads should be stored in a dry place.

**part 3 section a: tests****power factor tests**

Many operators find it advisable to make annual power factor tests, and at the same time, make a visual inspection of the mechanical condition of bushings. Others do not feel that an annual check is absolutely necessary and so make their inspections at greater intervals. However, the fact that the annual check is made by many progressive customers indicates its desirability.

Some of the early bushings do not have as high puncture strength as bushings of later designs. Also in some cases, the lower ends of the older types of bushings are shorter than those of later bushings. For these reasons their condition should be checked at shorter intervals than will be required by later designs. Older bushings in very important locations where an outage might cause a serious disturbance, should receive semi-annual visual inspection as described below. Annual power factor tests are desirable.

a. **Visual inspection:** Check for leaking compound or oil, mechanical damage, broken away cement, broken or cracked porcelains, accumulations of dirt on porcelain, or carbon on lower end, etc. If any of the above are found and cannot be removed by cleaning, the bushing should be removed from service. Leaking compound or oil even in small amounts is a potential hazard, because moisture may be drawn into the weather casing.

b. **Power factor and capacitance tests:** The power factor will indicate the dielectric losses and show the general condition of the insulation. The capacitance measurement is valuable to show if a weakness exists in any layer of the bushing.

The Westinghouse Corporation recommends checking all bushings periodically, and the immediate reconditioning or replacing of bushings which are indicated to be below normal.

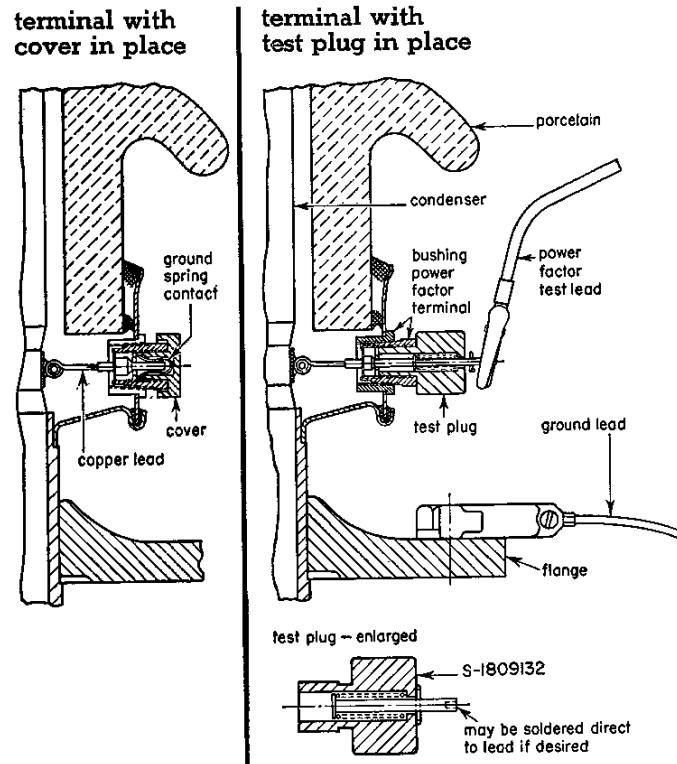

Power factor tests, while not absolutely necessary, or infallible, are the best check on the interior condition of the bushing. The information given in the following paragraphs is for customers who have adopted power factor testing, and who desire to take fullest advantage of its use.

Condenser bushing construction, as related to power factor testing, falls into two general classifications; bushings with solid stud conductors, and those with tubular conductors or leads. Both types are used on circuit breakers as well as on transformers. The tubular lead permits the use of a draw-through cable conductor on transformers, which is connected to the terminal cap of the bushing. The cable is insulated to withstand a 1000 volt test between cable and tube when disconnected from the bushing cap. Tubular lead bushings for circuit breakers carry the current directly through the tube, without a cable. Solid stud bushings, for both breakers and transformers, carry the current directly through the stud.

**insulating heads:** Some tubular lead bushings for transformers were supplied with insulating heads mounted on top of the bushing. This feature permits making power factor tests without opening the bushing terminal cap.

When power factor testing a transformer bushing with the insulating head, withdraw the contact screw in cap, connect the testing lead to cap and the shielding lead to the top of insulating head. After test, tighten the contact screw.

**ungrounded power factor methods:** The so called ungrounded power factor method can be made by attaching a test lead to the voltage tap receptacle on bushings 92 kv and higher and the power factor tap provided on ASA standard bushings 23 to 69 kv, inclusive. The ungrounded power factor methods provide power factor tests on bushings mounted in apparatus without disconnecting external parts such as transformer winding, etc. Refer to fig. 30 for type "S" ungrounded power factor tests and fig. 31 for type "O" power factor tests through voltage tap.

**figure 30:** Power factor testing terminal for making ungrounded power factor tests on type "S" bushings.

**caution:** *Do not remove terminal cover until bushing is removed from high voltage line and grounded.*

1. Remove terminal cover.
2. Proceed to make a power factor test in the conventional manner used for testing ungrounded specimen (power factor connection S-1809132 may be used).
3. Replace terminal cover.

**caution:** *It is extremely important that the cover be reassembled on the testing terminal before energizing the bushing.*

data

**33-360**

for power circuit breakers  
and transformers

page 25

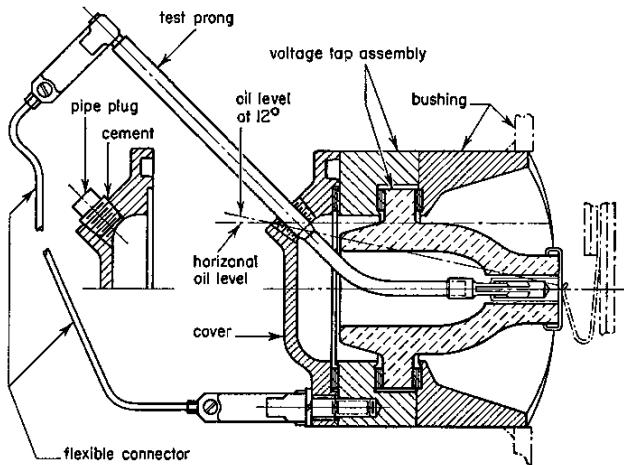

figure 31: Test prong for making ungrounded power factor tests through voltage tap on type "O" bushings.

## instructions

After bushing is disconnected from the high voltage line and grounded, the procedure for using the test prong is:

1. Remove the pipe plug in the voltage tap cover.
2. Connect the terminal end of the test prong to ground with a flexible connector, so an electrostatic charge left on the bushing after it has been removed from service will be discharged to ground when the test prong is inserted in the voltage tap.
3. Insert the prong through the hole in the cover to make contact with the female contact in the rear of the voltage tap assembly.
4. Disconnect the test prong from ground and connect it to the proper power factor test lead.
5. Proceed to make a power factor test in the conventional manner used for testing ungrounded specimens.
6. After completing the power factor tests, remove the test prong.
7. Add new Wemco "C" oil to have level even with bottom of hole in cover, if necessary.
8. Replace the pipe plug in a weatherproof manner in the cover.

## general procedure for power factor test:

When standard circuit breaker bushings are tested, the other parts of the breaker such as the lift rods, oil, grids, arc shields, etc., are included in the test and will influence the results. If a high power factor reading is obtained because of dirt or moisture on or in any part other than the bushing, the affected part should be cleaned and dried. In the case of arc shields, lift rods and guides, cleaning with benzine or carbon tetrachloride will usually lower the power factor to a satisfactory value. Oil which has a high power factor will cause bushings which are tested in it to read high on power factor test. Such oil should be investigated for dielectric strength, acidity, and RE test, and if any of these show the oil to be below normal, it should be replaced with oil in good condition. The gasket between the bushing flange and the circuit breaker or transformer base is an insulator, and the bushing is electrically connected to the base or tank by the mounting bolts. If paint under the heads of the bolts prevents their making good electrical contact, the bushing on test may indicate a high power factor.

The recommended way for testing circuit breaker bushings is to disconnect the bushings at the top, then test with breaker closed, and then each bushing by itself with breaker opened. The combined three readings will, after experience is obtained in interpreting them, definitely locate any defect which may be present.

With the extremely low normal power factor of the newer bushings, the influence of high power factor in the De-ion grids causes the bushing power factor measurement to be high. A high value of power factor in the grids does not affect their interrupting ability. If this condition is encountered, the losses of the De-ion grids may be eliminated by ungrounded power factor test method, shielding or removing from the bushing. They may be shielded by covering the grid with metal foil or with a screen of metal having a mesh not over 2½ inches square. The shield must make good electrical contact with the stationary contact foot.

Tests are not usually made on circuit breaker oil unless a high loss is indicated and then only after the bushings have been proven sound.

It is possible that high power factor may be caused by conducting surfaces in the proximity of the bushing. This is particularly true of spare bushings being tested in their crates. It is possible for the crate, especially if wet, or the tester himself to cause a high power factor reading. For this reason it is recommended that the bushings be removed from their crates for testing and all conducting surfaces eliminated from the immediate vicinity of the bushing.

Bushings suitable for ungrounded power factor tests may be tested in transformers without disconnecting the winding. Where ungrounded power factor methods are not available, the bushings may be tested in transformers by other methods.

For transformer bushing without the power factor test terminal or potential taps, where the draw-through lead with top cable connection is used and where it is possible to disconnect the transformer winding from ground, the bushings may be tested without removal from the apparatus providing the testing set is equipped to bring the tube and lead to the same potential and phase relationship. If there is a layer of tape on the lead such as is used in

**part 3****section a: tests****power factor tests continued**

present designs and has been used in most of the old designs this will be sufficient insulation to permit testing the bushing without removal. A thin wall insulating tube slipped down over the lead provides ample insulation for the top end of the lead.

If the transformer bushings have an insulating head and the testing set is equipped to bring the test circuit and the shielding circuit to the same potential and phase relationship, it will not be necessary to disconnect the internal bushing lead or the small length of outside line, but the transformer winding must be disconnected from ground.

If high losses are found it is best to determine their location before removal of the bushing; they can often be eliminated by cleaning some surfaces.

Power factors of bushings vary with changes in temperature. It is therefore desirable that the tests be made in warm weather with the apparatus not under 60°F. A record of the test should include the temperature of the bushing, as well as the ambient temperature.

The temperature of the bushing may be determined approximately by one of the following methods, if the apparatus has just been taken out of service.

- a. Use the mean of the air and top oil temperatures as measured by thermometers; the oil temperature to be measured at the top of and inside of the tank; the air temperature to be measured in the shade, at a point not less than 4 feet away from the tank.
- b. Measure with a thermometer the temperature on the outside of the tank at the level of the top of the oil and add 5°F to allow for the difference in temperature between that of the bushing and the outside of the tank.

If the apparatus has been out of service for a sufficient time to allow all parts to cool to atmospheric temperature, then the atmospheric temperature (measured in the shade) may be used.

The power factors at which apparatus should be withdrawn from service will of course depend a great deal on the seriousness of an interruption on the particular circuit.

Generally a bushing having a power factor measurement within the limits of the curves on page 27 will have a dielectric strength necessary to meet the standardized one minute acceptance test and will be satisfactory for service.

The best method for determining the condition of a bushing using power factor measurements is to compare several readings taken over a long period of time at approximately the same temperature. These readings should remain fairly constant. Any continual rise in the readings with time indicates that the bushing is deteriorating and it should be removed from service and checked to determine the cause. Where previous records are not available compare tests between similar bushings.

Bushings operated at extremely high temperatures either because of heavy loads on the apparatus, or because of the location in very hot climates will have larger losses than bushings operated

at lower temperatures. For this reason, it is recommended that curve 3 (see page 27) should be used in determining the safe power factor for bushings other than type "O" in such locations.

When field tests with the power factor testing set indicates that the condition of a bushing is questionable, the results may be referred to the Westinghouse bushing engineers for analysis and recommendations. Questions on transformer bushings should be referred to the Power Transformer Engineering Department at Sharon, Pa., and for circuit breaker bushings should be referred to the Power Circuit Breaker Department at East Pittsburgh, Pa.

There will be some difference in the safe power factors of bushings of different periods and constructions as the high power factors will arise from different sources. We would also take from service some types of bushings with known defects much quicker than others with recognized good construction. It is recommended that the factory be consulted in the case of any doubt in the interpretation of test results on any bushings.

When a bushing is used on a line having a rated circuit voltage lower than the nominal voltage class of the bushing, the power factor may be slightly higher than indicated by the curve and still be satisfactory, or if bushings are on circuits of a higher voltage, the power factor must be lower than indicated by the curve.

With normal capacitance the power factor is directly indicative of the watts loss in the insulation. The power factor shows the quality of the insulation. The watts loss is a composite indication of the quality and amount of insulation tested. The power factor can be used for direct comparison between a small bushing and a large one.

Capacitance is used in the bushing analysis only for comparison with other bushings of the same design and tested in similar apparatus. A capacitance value of more than 15 percent on all bushings of earlier make than the type "O" and 10 percent on the type "O" above the average of the other bushings of the same design raises a suspicion that some of the layers of the condenser bushing have been short circuited either through puncture or by leakage over the surface. The percentage of good layers remaining should vary inversely as the percentage of the capacitance reading to the average capacitance for the particular design of bushing.

The watts loss will not always show the condition of partial breakdown. Bushings with one or two percent power factor will be passed as satisfactory if only the watts are considered, even if thirty percent of the insulation is punctured. It would be rejected on the capacitance analysis on a comparatively small amount of short circuited insulation.

In case of a high power factor measurement, the most likely cause is that moisture has found its way inside the porcelain weather casing or that the lower end has been exposed to moisture in storage or to moisture and carbon in the oil. When it has been determined that the high power factor is in the bushing itself, the bushing must be removed from service. See recommendations applying to bushings of the type involved.

## power factor limits

**curve 1:** For type "S" and other condenser bushings of 69 kv and below used on circuit breakers and instrument transformers.

**curve 2:** For condenser bushings (except type "O") on circuit breakers and instrument transformers of 92 to 138 kv, incl.

**curve 3:** For type "S" and other condenser bushings (except type "O") all kv ratings used on power and distribution transformers. For condenser bushings (except type "O") on circuit breakers and instrument transformers on 161 to 288 kv, incl.

**curve 4:** For all type "O" condenser bushings 92 kv and above.

figure 32: Acceptable power factor limits for Westinghouse bushings.

**part 3****section a: tests****collar power factor tests**

To make power factor tests on a section of a bushing, a metal band may be placed around the bushing at some location and power factor taken between the metal band and center conductor. Example—a collar test between a metal band just beneath the top porcelain rain shed and the center conductor may show water in the top of a bushing that would not be detected on a power factor test on the complete bushing.

With power factor equipment high voltage lead connected to the metal band and the ground lead connected to the center conductor, the test is called "Hot Power Factor Collar Test". With the test leads reversed the test is called "Cold Power Factor Collar Test".

**moisture tests**

To test for moisture in bushings filled with compound, the following checks may be made. These checks will show 0.15% of moisture. (The tests are not applicable to bushings built before 1922 with the hard compound.) As the type "S" is hermetically sealed it should not be opened to test for moisture unless the bushing has high power factor. The type "O" should not be opened for oil examination unless power factor tests are above the acceptable limits, as shown on page 27.

To make the test, the cap is opened to expose the gum. One end of a red hot  $\frac{1}{4}$ " rod is pushed into the filling compound. If moisture is present a crackling sputtering or hissing noise will be heard. If no moisture is present the gum melts very quietly.

Another very effective test is to place some of the compound on a piece of wire and melt it in the flame of a match or a blow torch. The flame of the blow torch should be turned low so that the amount of noise present will be reduced. If there is moisture in the gum, a sputtering noise will be heard and small sparks will be thrown off. If the gum is dry, it will melt without disturbance. When water is found in the compound, the bushing should be taken out of service. See recommendations for bushings of that particular type.

For types "G", "G<sub>1</sub>", "G<sub>2</sub>", "K" and "K<sub>1</sub>" bushings, samples of compound for the moisture test may be obtained on a small dry stick or rod inserted through the top filling plug.

For type "S" bushings, small samples of the compound can be obtained by unsoldering the screw in the side of the cap and inserting a wire.

Check oil or Inerteen height in types "OG" and "IG" bushings at regular inspection periods and "OS" (where gauges are provided).

On all the later type bushings, except types "S" and "O", a pipe plug is provided so that a pressure test of 15 pounds with a dry air or gas can be applied to locate possible moisture leakage on high power factor bushings. A pressure gauge left for at least 15 minutes with line closed after the outside pressure is removed will show definitely if the bushing is tight. The use of oil or soapy water over suspected parts will show large leaks.

The pressure test should not be applied to the types "O" and "S" bushings. If power factor measurement indicates them to be defective, they should be taken to a repair shop where they can be thoroughly investigated.

**section b: maintenance****general procedure**

General maintenance of bushings should include periodic visual inspection for physical damage, leaks, bad connections, etc. The bushings should be cleaned at intervals to keep the insulation surfaces free from accumulation of foreign materials. Paint exposed metal parts to protect from the weather.

See part 2 for any specific maintenance information for various types of bushings.

If power factor testing is used, the power factor and capacitance should be measured at intervals suggested for particular type bushings or established by service conditions.

If a bushing is damaged or defective, repair or replacement should be made.

A decision between repair or replacement must often be made by the customer. To make this decision he must know the Corporation's policy on the repair or replacement of bushings and the price of the repair or replacement. It is highly desirable that the customer make this decision before he incurs any expense to send the bushing to the factory.

When the differential of price between the repair of the older types and their replacement with up-to-date bushings is balanced against the improvements of the later designs, it is desirable that all bushings except those of the later types ("G", "G<sub>1</sub>", "G<sub>2</sub>", "M", "K", "K<sub>1</sub>", "CT", "N", "O" or "S") be replaced rather than repaired.

When a bushing is to be repaired, it should be returned to the factory (transformer bushings to Sharon, Pa., and circuit breaker bushings to East Pittsburgh, Pa.) Information as to the cause of the return should accompany the bushing.

A few of the advantages obtained by returning the bushing to the factory for repair are as follows:

- a. The proper processes, gasket materials, filling compounds, cements, etc., are used.
- b. Whenever possible, the bushings are changed to latest construction and all gaskets are renewed.
- c. Pressure tests are made to insure tightness of the condenser and the weather casing assembly.
- d. Power factor tests and 60 cycle routine tests are made. A bushing which cannot be processed to have a power factor less than two percent is rejected. A repaired bushing must withstand the same 60 cycle voltage test as a new bushing of the same design.
- e. Experienced workmen and special facilities are available.
- f. A bushing repaired at the factory carries the same warranties as a new bushing of the same type.

If the above schedule for testing and maintenance is followed, and bushings renewed or replaced as per recommendations given, we believe condenser bushing failures will practically disappear.

**potential tap for use as voltage source:** The primary purpose of the potential tap, fig. 33, on type "O" bushings is to provide a source of voltage for use in synchronizing, relaying, etc. Figure 34 shows potential device cable attached to a bushing. This cable may be obtained from East Pittsburgh. When using this connector, the potential tap socket cover must be removed from the bushing and the oil replaced with petrolatum. Sufficient petrolatum should be packed in the tap socket so that the cavity is almost full when the connector is in place. The one end of the connector has provisions for clamping it in place, using the same holes and bolts as for the cover of the voltage tap socket. Provisions are made for connecting the other end to the potential device cabinet.

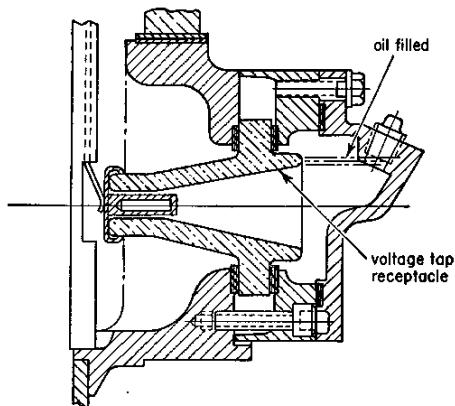

figure 33: Voltage tap receptacle for type "O" bushing

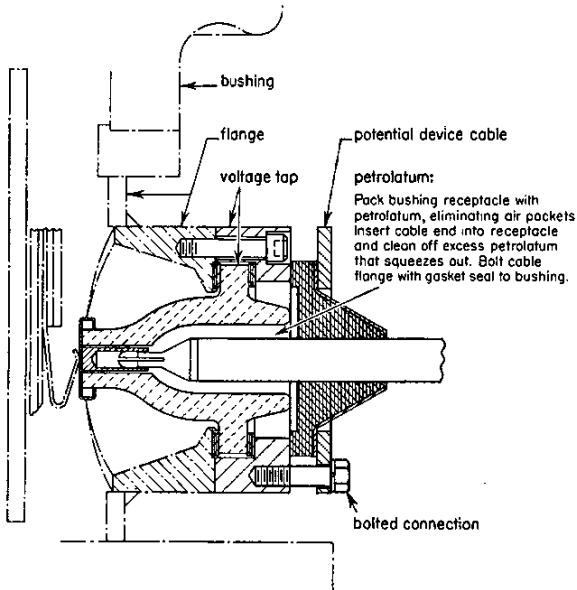

figure 34: Voltage tap, bolt connected, for type "O" bushing

## potential device connection

Two layer tapped bushings have been supplied since 1934 to use the type PB-2, PBA or PBA-2 potential devices. Attachment of potential device cable to the modern bushing receptacle is made as shown in fig. 1 of I.B. 33-357-2 for adjustment. By making several modifications as shown in fig. 35, the early types PB-1 and PB-11 single-layer tap potential devices can be attached to modern two layer tap bushings. See instruction book above for adjusting PB-1 and PB-11 to two layer taps.

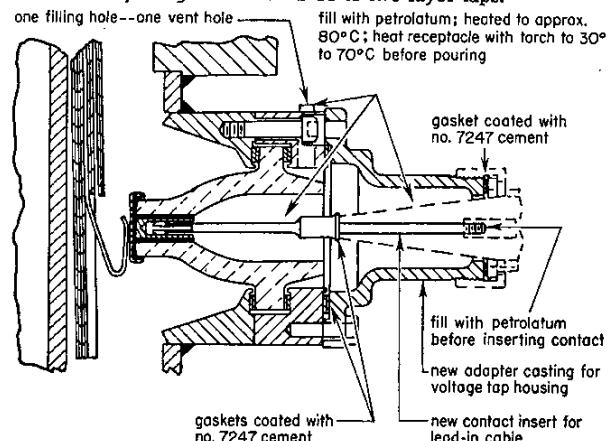

figure 35: Voltage tap connection for PB-1 and PB-11 networks.

## bushing filling plastic 7399-1

The purpose of a filling material (compound or oil) in the Westinghouse Micarta condenser bushing is not to develop and maintain its electrical strength but rather to protect the surface of the condenser and to prevent flash-over inside the porcelain when impulse voltages or excessive 60 cycle voltages reach the terminals. Bushing plastic 7399-1 was developed by Westinghouse Electric Corporation for this use in 1938 and has been used since that time on both new and repair orders.

This compound is a black asphalt-oil-aeroclor plastic material, which is heavier than water at all operating temperatures. The plastic will not flow readily at room temperature but is quite fluid when heated to  $125^\circ \pm 5^\circ\text{C}$  (never heat over  $135^\circ\text{C}$ ). This material will not crack or pull away from the condenser or porcelain at temperatures as low as  $-50^\circ\text{C}$ .

The Westinghouse standard condenser bushings 69 kv and below are all compound filled. The principal advantages of compound filling over oil filling are (1) it greatly minimizes the possibilities of fire on top of transformers and breakers in case of porcelain rupture, (2) the compound flows slowly and will remain on the bushing Micarta for a considerable time even though the porcelain is broken, and (3) the compound being heavier than water protects the upper end of the bushing even should moisture enter the weather casing.

Old bushings using compound 3172 should have the filling material changed to bushing plastic 7399-1 when bushings are being repaired or rehabilitated. The porcelain and Micarta must both be thoroughly cleaned before the bushing plastic is applied and it is preferable that this work be done at the factory.

**part 3 section b: maintenance****prevention of oil leaks**

types "F", "G", and "K" bushings installed on Sealedaire® and Inertaire® transformers

For bushings built up to and including year 1939. For a few years, a metal-to-metal seal was used between the end of the copper tube through the condenser, and the terminal cap. This seal depends on the end of the tube being smooth and round and on a smooth taper in the cap accurately centered. As the cap is tightened, a line contact between the tube and cap taper is depended upon to be tight.

In general, this expectation has been met. Occasional difficulty with this requirement in the field has been due to the fact that many bushings are now subjected to pressure after installation, which would not have been formerly, because of the use of Sealedaire. The Sealedaire feature now provided on power transformers, 2000 kva and below, will subject the bushings to increased pressures after installation. Therefore, special care must be taken in installing the terminal cap if leakage is to be prevented.

There are two principal causes for leakage. One is failure to tighten sufficiently. The other trouble is mechanical damage, such as nicks and other damage to the tube, and also galling and grooves in the taper inside the terminal cap.

Where leakage of oil at this spot exists in the field, it is recommended that any pressure in the tank be released. Then the cap should be inspected for mechanical damage. If such exists, it should be repaired if possible. If the tube is damaged, this can usually be repaired in the field. If the terminal cap is galled, a new one may be obtained from the factory. Tinning of the inside surface of the terminal cap will sometimes correct the trouble where the surface is only slightly damaged. An alternate method is to supply the new gasketed type of seal, as described below.

If it is reasonably certain that the cap is not tight, it may be decided not to inspect the parts but to tighten and test. Care should be taken not to tighten too much, as this will gall the tapered surface and require both repairs to the tube and a new cap. After tightening, a pressure of five pounds per square inch should be applied in the air space and the cap tested with soapy water.

For bushings built for transformers for the years 1940-41, a gasket seal is used at the top of the condenser tube.

To replace the older type of seal with the gasketed type, the old terminal cap may be used, but it is necessary to obtain the gasket and sealing thimble from the factory (Sharon). Soldering of the contact plug into the tube, in the field, is required. When such a field change is found desirable, full instructions will be given upon request to the factory.

**section c: repair****general procedure**

Bushings manufactured prior to 1934 should be replaced with bushings of modern design whenever their condition, as indicated by visual inspection, or power factor and capacitance tests shows them to be in need of servicing. We also advocate replacement of the bushings manufactured prior to 1934 with bushings of a modern design in case the apparatus is undergoing any major rehabilitation.

When replacing old bushings we recommend using modern bushings. In some cases because of space limitations, it will not be possible to provide such bushings impulse co-ordinated even when equipped with standard gap spacings. Adapters are required in some cases to fit modern bushings to old apparatus. When necessary, they are supplied with the replacement bushings.

Condenser bushings can be rebuilt successfully by the customer, if proper facilities are available, and if the instructions for rebuilding are carefully followed by capable and experienced workmen. However, the best results are usually obtained by having the work done by East Pittsburgh or Sharon plants of the Westinghouse Corporation. Many of the Corporation's service shops are also well equipped to do the work in an excellent manner. The equipment required for rebuilding should include 60 cycle and power factor testing equipment. Ovens of a suitable size equipped with temperature control up to 110°C are necessary. A liberal change of air in the ovens is necessary. Presses for flanges and caps are essential to obtain the best results. Lathes of a size suitable for swinging the bushings are also needed. Small tools, taps and dies must be at hand. Facilities for handling the filling compound at a proper temperature must be available. For the larger bushings some crane service is also needed.

**instructions for repair,  
test, and re-assembly**

At the factory the following operations are generally followed on all except type "O" bushings. For type "O" bushing repair information, see IL 33-354-1; for type "S", see IL 33-354-2.

- a. Take power factor and capacitance readings of the bushing as received to determine its condition. (If power factor under 4%, make 60 cycle test).
- b. Remove porcelain and compound.
- c. Repeat power factor and capacitance test.
- d. If power factor of condenser alone is under curve 1 and over curve 3 of page 27, the varnish is removed and the condenser baked to a power factor under curve 3.
- e. Re-varnish and pressure test the condenser for tightness.
- f. Gaskets are replaced with new ones made of cork neoprene.

for power circuit breakers  
and transformers

technical  
data

33-360

page 31

- g. Top castings are tested for leakage.
- h. Re-assemble.
- i. Repeat 60 cycle test.
- j. Repeat power factor test.
- k. Inspection.
- l. Tape and dip lower end for moisture proofing if stored.

**repair:** For types "A", "B", "C", "D", "E", "F", "H-1" and "H-2": The recommendations are always that no repairs be made but bushings be replaced.

For types "G", "K", "M" and "N": Repairs are made as per original construction.

- a. Remove the cap and detachable metal parts at the top.
- b. Tape over threads.
- c. Invert the bushing in a warm place or oven and the compound will gradually flow out.
- d. Remove porcelain.
- e. Clean condenser and inside porcelain using benzine or similar material.
- f. Air test at 15 lbs per square inch the condenser and flange.

For bushing originally built with the old 3172 compound it is necessary that the porcelain be entirely cleaned of the old compound.

**tests:** Make power factor and capacitance tests on condenser. If the power factor meets curve 3 of page 27, the condenser is satisfactory. The gloss should then be removed from the old varnish by sandpapering and two (2) coats of varnish 7623-1 applied at both ends of the bushing. Bake each coat at 90°C for 4 hours. This varnish will give renewed moisture protection to the bushing and provide a covering entirely inert to the bushing plastic. The old varnish may be somewhat softened by the plastic at those spots where it has not been completely oxidized due to the varnish coat being too heavy.

If the power factor is over curve 3 on page 27 but not over curve 1, scrape and sandpaper off varnish, being careful not to remove any of the Micarta and then bake in an oven with free circulation and a temperature of 95°C ± 5°C for periods as given below.

For 25°C power factor 2.00 to 2.25% bake 4 days  
For 25°C power factor 2.26 to 2.50% bake 6 days  
For 25°C power factor 2.51 to 3.00% bake 10 days  
For 25°C power factor 3.01 to 3.50% bake 12 days

After baking, cool for 24 hours before rechecking the power factor. If the condenser has not then returned to a value below curve 3, its use is not recommended.

If power factor of the condenser alone is over the curve 1 on page 27, it is questionable whether the condenser can be brought to a reasonable power factor by drying and also whether a bushing so reclaimed has entirely regained its insulating properties.

The capacitance should not be over 10% higher than the average of similar bushings or there is a suspicion of short circuited layers. The bushings should then be given 6 coats of 7623-1 varnish.

Dry each coat as specified above—sandpaper lightly each coat as necessary to maintain a smooth glossy finish.

Weather casing assemblies should be air-tested at 15 lb per sq. in.

**re-assembly:** Clean carefully all gaskets and gasketed surfaces. Except for screwed connections use cork neoprene gaskets 7249-1, in all cases. Gasket stops should be used on bushings where the spring follow-up on gaskets is provided. The cork neoprene gasket is applied with a thin even coat of 1887 or 6277 cement which is allowed to become tacky before placing in position. The asbestos neoprene stop gasket is coated with aluminum paint and then dried and then cement is used. Metal covered asbestos gaskets are applied with 6855 shellac which should not be allowed to become tacky.

Assemble with approximately 250 lb per sq in on the cork-neoprene gasket of largest dimension. Where gasket stops are used, this should just bring the gasket stops into close contact with porcelain and metal.

In packing the stuffing box of type "G" bushings, insert one ring at a time and tamp firmly in place before adding the next ring. Stagger the joints of the packing rings. Before screwing in the packing nut, add sufficient amount of the sealing material 6008 to fill under the nut. The packing nut should be drilled with two small holes to permit the surplus of material to be forced out. Screw packing nut tightly. Cover with 6008 sealing compound. Use 6855 cement on the metal and asbestos gasket under the top nut. Use only alcohol and rosin for soldering flux when soldering top nut.

Where oil is used as the filling for weather casing and wherever the plastic encased bushing is completely assembled before filling from the bottom, the bushing should be baked in 90°C ± 5°C oven for 3 hours to set the gasket cements and also to make them thoroughly oil proof. When filled with hot plastic compound, pour immediately after the bushing is removed from the oven. The approximate height of filling compound when at 20°C to 25°C is as per the sketches, part 2, of the various type bushings. There should be at 20°C to 25°C from  $\frac{1}{6}$  to  $\frac{1}{5}$  as much air space in cap and porcelain as there is plastic.

It is desirable in bushings 92 kv and above, where filling plug is provided at flange that the filling be from the bottom in order

**part 3****section c: repair****re-assembly continued**

to avoid trapping of air in the filling. The filling plug at flange is supplied on some of the type "G" and all of the type "K", "M" and "N" bushings. When filling with plastic from the bottom the vent at the top must be open and the weather casing filled until the plastic runs out of the top vent. While still hot, plastic must then be drained off from bottom vent as follows to provide the correct expansion space in cap.

92 kv	1 3/4 pints
115 kv	2 1/2 pints
138 kv	3 3/4 pints
161 kv	4 1/2 pints
196 kv	6 pints
230 kv	8 pints
287 kv	10 pints

When filled with oil, the oil level at 20 to 25°C should be at middle of the glass for type "M", at 25°C level for type "K", and for type "ON" 1 1/8" above bottom of glass for 92 to 161 kv and 1 3/4" above bottom of glass for 196 to 288 kv bushings.

For the type "S" bushing, the plastic is entered at the filling plug at flange until it runs out vent hole at the side of the cap. This will give the correct amount of plastic and none need be drawn off.

For type "O" bushings the pointer of magnetic oil gauge should be horizontal at 20 to 25°C.

Make air tests, power factor and capacitance tests and where possible, 60 cycle, one minute, withstand tests.

**special precautions**

- a. Have surfaces for gaskets clean and free from oil or grease.
- b. Do not heat bushing plastic over 135°C.
- c. Where joints are bolted, tighten evenly all around, tightening each bolt a small amount each time.
- d. Use only bushing plastic 7399-1.
- e. Do not repair bushings where oil is found in the compound unless the point of entrance is found and closed.
- f. Be sure that air space is left over plastic as specified above.
- g. Paint over edges of all exposed gaskets.

**section d: storage**

Outdoor condenser bushings when installed in circuit breakers or transformers, are not sensitive to weather or atmospheric conditions, because the lower end is kept immersed in oil which prevents it from coming in contact with excessive moisture and the upper end is sealed. In storage other means must be employed to protect the lower end. The exception to this is the type "O" bushing which is weather proofed all over and the following paragraphs do not apply to type "O" bushings. Type "O" bushings should be stored vertically or with cap end at least 10" higher than inside end and protected from mechanical injury.

Types "S" and "OS" bushings shipped separately from the apparatus with which they are used have the lower end covered with a polyethylene bag containing silica gel crystals. This serves as a protection against moisture and dirt. This protection should not be removed until the bushing is placed in the apparatus, or the lower end is placed under oil for storage, unless moisture is seen inside the bag. (This bag is transparent and moisture may readily be seen without removing.) For long storage periods where moisture is detected in the bag, the bag may be removed, the bushing and bag dried and the bag recharged with dry silica gel. This bag should be removed before making power factor tests. The storage place should be clean, very dry, ventilated, and several degrees warmer than the outdoor temperature to prevent condensation. Do not store in cellars, outside sheds, or similar places.

The condition of the stored bushing can best be determined by the power factor test. Periodic tests showing a high or increasing power factor indicate improper storage conditions. Such bushings should be moved to better storage. A power factor test measurement made before putting a stored bushing in a breaker or transformer will give additional assurance that the bushing is suitable for service.

**part 4**

**identification of bushings  
by key numbers**

**section a:** information on bushing identification, replacement, and interchange ..... page 34  
nominal current ratings . . . page 34

**section b:** sketches for key number dimensions ..... page 35  
tabulation of key numbers ..... pages 36-44

**part 4 section a: bushing identification, replacement, and interchange****identification of bushings**

Most bushings are identified by nameplates mounted on the flanges or on the bushing caps. The bushing design is identified by drawing number (dwg no.) or style number (S#). Recent designs may have the drawing and group number (dwg \_\_\_\_ gr. \_\_\_\_).

The shop order (S.O.) or general order (G.O.) on which the bushing was built is usually given on the nameplate.

The above numbers should be referred to when writing to headquarters about a bushing. In addition, the S.O. identification and rating of the breaker or transformer should be given.

Since 1934, when power factor testing at the factory came into general use, bushings have been identified with serial numbers, following the S.O. number. For example, three bushings, built to dwg no. 31-A-815, gr. 1, on order number S.O. 70-K-472, would be marked:

dwg 31-A-815 gr. 1; S.O. 70-K-472—1  
dwg 31-A-815 gr. 1; S.O. 70-K-472—2  
dwg 31-A-815 gr. 1; S.O. 70-K-472—3.

In this way, a record of location and tests on individual bushings may be kept.

Since 1940, bushings have been further identified by kv rating and type letter on the nameplate. The nameplates of bushings supplied today also specify the key number where such has been assigned. For circuit breaker bushings, the ampere rating is also given on the nameplate. The ampere rating of a transformer bushing cannot be specified as it is generally dependent on the size of the draw-through lead.

**key numbers for condenser bushings** A key number has been assigned to most of the outdoor bushings for the purpose of identifying the principal mounting dimensions, internal dimensions and nominal current ratings. Bushings of the same key number will fit into the same apparatus without any change internally in the apparatus or bushing except as specified in the notes of the bushing tabulations pages 84 to 87. For obsolete circuit breaker bushings having porcelain arc shields on the lower end of the bushing, the arc shield is interchangeable where the same key numbers apply except as indicated in the notes on the particular bushing.

Transformer bushings having the same key numbers but different type letters may require a new terminal stud at the top of the draw-through cable, where cables are used. In some cases a longer cable is required. New bushings which are ordered to replace older types are furnished with the necessary cables and terminals.

Bushings of the same key number may have entirely different outside structures as, for instance, the method of connecting leads may be different; the height outside apparatus may be different; the voltage tap connection may be of one or two layers or non-existent; the receptacle may be of the screwed type with Moldarta insulation or the bolted type with porcelain insulation; the porcelain may be of standard or oversize height; the type of weather casing may be different, etc.

If it is necessary to refer to the factory concerning a bushing which does not have a nameplate, or if it is not possible to obtain the nameplate reading, the nameplate reading of the transformer or circuit breaker will usually be sufficient.

Figures 36 to 44 and tables following give the major dimensions of all present key numbers and list all bushings of each key number.

*how to locate dimensions, replacements, bushing number; and identification of interchangeable bushings:*

**1. when key number is known . . .**

- a. Refer to pages 36-44 for listing of dimensions and interchangeable bushings by drawings.
- b. All bushing drawings listed with same key number are interchangeable.

**2. when drawing number is known . . .**

- a. Refer to part 5, section a, pages 46-83, for key number and latest replacement bushings.

**nominal current ratings**

Current ratings of bushings as given in the table, parts 4 and 5 of this manual, are "nominal" current ratings. Actual current ratings depend upon the temperature of the surrounding media in which the bushing operates, that is, the temperature of the ambient air and oil surrounding the bushing. Nominal ratings given are for conditions as follows:

a. **transformer bushings**, lower end in 95°C oil and upper end in ambient air at 40°C with a maximum hot spot not exceeding 105°C. Lowering either the oil or ambient air temperature will allow the transformer bushing to be uprated above the nominal current and vice versa. For this reason operating conditions are an important consideration when applying bushings.

b. **circuit breaker bushings** are maximum ampere rated.

① For circuit breakers, use oil height as per oil gauge on tank.

② See note on nominal current ratings on page 34.

③ On drawing 340909, C = 4 1/2, kv = 7.5, amp = 1000.

# outdoor bushings

4.3 to 345 kv

① For circuit breakers, use oil height as per oil gauge on tank.

② See note on nominal current ratings on page 34.

③ Special for Public Service Co. of N. J.

④ These drawings require flat flange ring.

⑤ Flat seat.

① For circuit breakers, use oil height as per oil gauge on tank.

② See note on nominal current ratings on page 34.

③ L dimension is approximate only for these bushings.

④ L-T-R approximate only for these bushings.

⑤ 1 1/2-14 thirds at ends of bushings.

⑥ Bevel seat.

⑦ Insulated cable lead.

⑧ Flat seat.

⑨ At 25 cycles.

① For circuit breaker use oil height as per oil gauge on tank.  
② See note on nominal current ratings on page 34.

③ Flat seat.

④ Insulated cable lead.

⑤ L = 19 1/2.

⑥ L = 22 3/8.

⑦ Has 1 1/2-14 threads both ends.

⑧ L = 25 1/4.

⑨ L, T, and R dimensions are approximate only.

⑩ May be tube lead.

① For circuit breakers use oil height as per oil gauge on tank.

② See note on nominal current ratings on page 34.

③ L and T dimensions are approximate only.

④ S #590 448 only.

⑤ 6A8445 has larger diameter than others of Key 562.

⑥ 15A6957 has larger diameter than others of Key 562; has 2 layer voltage tap.

⑦ Angle flange.

⑧ 77 kv.

⑨ S #590 449 only.

① For circuit breaker use oil height as per oil gauge on tank.

② See note on nominal current ratings on page 34.

③ Additional inside length when transformer ball is used.

④ L = 36%, R = 2 1/4.

⑤ Angle seat.

⑥ Not adapted for circuit breaker arc shields.

⑦ Except tubular lead.

① For circuit breaker use oil height as per oil gauge on tank.

Key numbers 751 to 754 inclusive: In type "O" bushing the "W" dimension is as per fig. 40 to 43.

② See note on nominal current ratings on page 34.

③ Additional inside length when transformer ball is used.

④ Not adapted for circuit breaker arc shields.

⑤ 400 amps.

⑥ Have 15½ BC, 6—1-inch bolts; also 16¼ BC 8—¾-inch bolts.

⑦ Kv = special 161 kv porcelain—increased insulation thickness.

⑧ L = 51½, R = 2½.

⑨ L = 43½, A = 2½.

① For circuit breaker use oil height as per oil gauge on tank.

Key numbers 755 and 756 inclusive: In type "O" bushing the "T" dimension is as per fig. 40 to 43.

② See note on nominal current ratings on page 34.

③ Additional inside length when transformer ball is used.

④ Bolt circle = 23 1/2, number of bolts = 12.

⑤ 400 amps.

⑥ L = 51 1/16, R = 2 1/4.

⑦ Not adapted for circuit breaker arc shields.

# **part 5**

## **tabulation of Westinghouse bushing drawings from 1909 . . . engineering data and recommendations for spares and replacements**

**section a: tabulation of  
drawings . . . . . pages 46-83**

**section b: notes referring to  
tabulation . . . . . pages 84-87**

We have listed by numerical order of their assembly drawings, all of the important designs of outdoor bushings manufactured by the Westinghouse Electric Corporation since the first of these designs were brought out in 1909. Some few sizes having a very low activity have been omitted.

Recommendations for any bushings not included may be obtained by request to the Transformer Engineering Department at Sharon, Pa., or the Power Circuit Breaker Switchgear Engineering Department at East Pittsburgh, Pa.

Where slight departures from the recommendations are necessary, detail notes, designated by footnote symbols, will be found at the bottom of the page.

For convenience in locating the recommendations for any bushing, a column headed "refer to page" has been provided from which the user may readily obtain the page numbers containing the instructions applying to any particular bushing.

Where designs for replacement or spare bushings have already been made, the drawing number is given as well as the drawing number for the adapter if one is required. Where the ① appears it indicates that new drawings must be made. Where new designs are required and not shown, they will be prepared as required. Bushing replacements are usually made with present standard designs using adapters where necessary. When an order is entered for bushings it should state specifically a style number or shop order number of the transformer or breaker, and serial number of the transformer, as well as the identification on the bushing nameplate so that the proper bushing (with adapter if required) will be supplied.

Bushings listed as replacements should be checked in the table for later replacements.

It is possible that several bushings might be interchangeable.

When ordering a replacement from the factory, specify drawing, groups, and serial number of bushing to be replaced, shop order number (S.O. #) of breaker or transformer in which bushing will be used, and recommended replacement drawing number from the following tables. Only the newest replacement should be used.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Use an adapter when the old bushing has an angle flange.

⑤ Without jaw, dwg 17A3906 Gr. 1,2.

⑥ Key 683 has flat seat; Key 684 has angled seat.

⑦ Semi-condenser replacement bushing, for use only where standard type S cannot be applied.

⑧ For breakers with current transformers less than 5½" I.D. use dwg 17A2868 Gr. 5.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Semi-condenser replacement bushing, for use only where standard type S cannot be applied.

⑤ For some applications this bushing was built with solid stud (type I-2).

⑥ Or dwg. 15A6365 with 2-layer tap.

⑦ 450-785-1210-1710-2280 amps depending on size of stud.

⑧ 785-1210-1710 amps depending on size of stud.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Non-magnetic adapter similar to dwg 36B374.

⑤ 450 amps for solid stud lead.

⑥ Type "O" bushing—dwg 15A4987, Gr. 1, with one layer tap.

# outdoor bushings

4.3 to 345 kv

for power circuit breakers  
and transformers

technical data

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Type "O" bushing—dwg 15A4897, Gr. 1 with one layer tap.

⑤ To replace 662771 on type HS breakers use dwg 21A9879, Gr. 1.

⑥ Semi-condenser replacement bushing, for use only where standard type S cannot be applied.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Has special top terminal. Replacement key 707.

⑤ Replace with dwg 82B9 (220 amps); dwg 64B381 (370 amps); dwg 81B37 (485 amps).

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made

④ Plus insulating head dwg 8A9554.

⑤ With magnetic oil gauge.

⑥ For bushing with oil gauge use dwg 11B2755, Gr. 1.

⑦ Has special top terminal.

# outdoor bushings

4.3 to 345 kv

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Two conductor bushing.

⑤ Drawing 11A2115 with two leads.

⑥ Limited by steel flange.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Limited by steel flange.

⑤ Twin conductor bushing, same mounting as dwg 5A4338.

⑥ Twin conductor bushing, same mounting as dwg 9A6238.

⑦ Limited by slotted flange.

⑧ Semi-condenser replacement bushing, for use only where standard type S cannot be applied.

⑨ Twin-conductor bushing.

⑩ Inverted pothead bushing.

④ See note on nominal current ratings on page 34.

⑤ Refer to pages 84 to 87.

⑥ Drawing not made.

⑦ Limited by steel flange.

⑧ C 9 1/4 - 8 1/2

⑨ Special for Detroit Edison Co. Has 1 1/16 longer flange setting.

⑩ Special for public service of New Jersey.

⑪ Has glass oil gauge.

# outdoor bushings

4.3 to 345 kv

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Limited by steel flange.

⑤ Limited by slotted flange.

⑥ Special for Detroit Edison Co.

⑦ Special for Public Service of New Jersey.

⑧ Special for Penn Railroad.

⑨ Use to replace dwg 662271 on type HS breaker only.

⑩ Has 70 inch creepage.

⑪ Has shielded layer.

⑫ Special top terminal for Southern California Edison Co.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Limited by steel flange.

⑤ Special for Baltimore Electric and Gas.

⑥ Special for Southern California Edison Co.

⑦ Special top terminal—L = 1½—12 th'ds for Bonneville Power Administration.

⑧ First group is for use in oil. Second group for use in Inerteen®.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Has two B C.

⑤ Has 92½ creepage.

⑥ Special for telescoping disconnect switch.

⑦ First group is for use in oil. Second group for use in Inerteen.

⑧ Has pt terminal.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Special for Southern California Edison Co.

⑤ Special for Baltimore Gas & Electric

⑥ Special for Pacific Gas & Electric.

⑦ Inverted pothead bushing.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Limited by steel flange.

⑤ For breakers with current transformers less than 5½ inches I.D., use dwg 17A2868, Gr. 1.

⑥ Adapter included in dwg 17A2868 Gr. 3.

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Drawing not made.

④ Limited by steel flange.

⑤ 1 1/4" dia. stud machined to 1 1/2" dia. both ends.

⑥ Bushing has fusible link inside bushing tube.

# outdoor bushings

① See note on nominal current ratings on page 34.

② Refer to pages 84 to 87.

③ Limited by slotted flange.

**part 5****section b: notes referring to tabulation**

1. This bushing has considerably less insulation thickness than is used on present designs.
2. Bushing key #652 with proper adapters can be used to replace bushing dwg 279304, 279323, 363131 and 419892.
3. Requires also new arc shield assembly.
4. Replacements recommended have 600 amp rating.
5. A new drawing with a 34.5 kv rating may be used as replacement if service voltage and line protection are not over 34.5 kv class. If a bushing with 46 kv insulation is used, the current transformers and perhaps their mountings will need to be changed to ones of larger diameter.
6. Replacement must have flat flange seat.
7. This bushing has the single seal stuffing box and construction does not permit modification. Replacement is recommended.
8. The bushings with triple seal of type "F" can be distinguished if they have any or all the following features:
  - (a) A plugged pipe tap for air tests.
  - (b) A plain ring (not an angle ring) cemented to the top of the porcelain.
  - (c) The top of the upper nut is  $1\frac{3}{8}$ " or more above the upper surface of the stuffing plates.
  - (d) Soldering of top nut to stud.
9. The suggested replacement bushing is provided with a detachable bevel ring which makes it suitable for either a beveled or flat seat on the cover boss. In some cases it may also be necessary to shorten lower thread end.
10. The bushings of triple seal of type "F" can be distinguished if they have any of the following features:
  - (a) A plugged pipe tap for air tests.
  - (b) A plain ring (not an angle ring) cemented to the top of the porcelain.
  - (c) The top of the upper nut is  $1\frac{1}{2}$ " or over above the upper surface of the stuffing plate.
  - (d) The top nut is soldered to the stud.
11. The replacement bushing has 265 kv average dry F.O.
12. The bushing of triple seal of type "F" can be distinguished if they have any or all of the following features. Otherwise, it will be necessary to check factory for the particular S.O.
  - (a) A plugged pipe tap for air tests.
  - (b) A plain ring (not an angle ring) cemented to the top of the porcelain.
  - (c) The top nut is soldered to the stud.
13. This design has oversize porcelains.
14. This design has single seal stuffing box. Bushings should be rehabilitated.
15. Any rebuilding should be done at the factory.
16. Addition of tube seal as per dwg 45-B-129 is recommended for bushing dwg 660900 and 662766.
17. Part 5, section a, specifies a one layer tap for the replacement bushing. If a two layer tap is required for possible future use with a PB-2 or PBA potential network, but for present use on PB-1 or PB-11 network, the factory should be consulted for necessary modifications and adjustments, see page 29. If the two layer tap is required for use only with the PB-2 or PBA potential network, merely specify this in the order.
18. S# 1019225, dwg 82-A-409 and S# 1040675, dwg 93-A-964 have one layer tap. S# 1019226, dwg 82-A-409 and S# 1040676, dwg 93-A-964 have two layer tap.
19. S# 1019225 has one layer tap. S# 1019226 has two layer tap.
20. Original bushing has lower threads  $2\frac{1}{4}$ " long while replacement bushing has lower threads  $3\frac{1}{4}$ " long.
21. Original dwg has voltage tap receptacle which requires special potential network cable. The special network cable will not fit specified replacement.
22. Replacement bushing can be adjusted for use with PB-1 or PB-11 network by proper adapters on voltage tap receptacle and change of contact plunger in cable.
23. If clamp type arc shield hood, grounding of flange hood is necessary.
24. Bushing key #652 with adapter dwg 623080 can replace bushing key #683.
25. Requires special tapping of voltage tap receptacle, to fit same potential network cables as for original bushing.
26. Bushing key #682 (1200 amp CB rating) can replace bushing key #681 (600 amp CB rating).
27. This bushing has porcelain of higher voltage class.
28. Proposed replacement has stud; original had tubing.
29. The arc shield hood of replacement bushing must be used.
30. The original bushing has external oil reservoir.

and transformers

technical  
data

**33-360**

page 85

31. S#590449 is 1200 amp—uses key #556. S#590448 is 600 amp—uses key #562.
32. Bushings of 1200 amp rating, key #556, can be used to replace 600 amp rating, key #562.
33. S#487109 is 1200 amp and uses key #570. S#511820 is 600 amp and uses key #564.
34. Bushings of 1200 amp rating, key #570, can be used to replace 600 amp rating, key #564.
35. This bushing is larger diameter on inside of apparatus than others with this key #562 and cannot replace the others but the others may replace this.
36. S#587967 is 600 amp rating. Others of this key number have 1200 amp.
37. S#918721, 415833 and 280679 are 300 amp key #464 and S#918722 is 600 amp key #463.
38. Is oil encased type with "M" cap but no glass gauge.
39. S#1124178, key #353, has bevel seat on flange.  
S#1173218, key #354, has flat seat on flange.  
S#1114918, key #354, has flat seat on flange.
40. S#940083, key #353, has bevel seat on flange.  
S#940084, key #354, has flat seat on flange.
41. S#1124174, key #353, has bevel seat on flange.  
S#1124175, key #354, has flat seat on flange.
42. S#1114917, key #353, has bevel seat on flange.  
S#1114918, key #354, has flat seat on flange.
43. S#486824 and 486825, key #353, have bevel seat on flange.  
S#486822 and 486823, key #354, have flat seat on flange.
44. For 1912 type with obtuse angle flange use adapter dwg 10-A-923. For 1913 type with right angle flange use adapter dwg 10-A-927.
45. Requires modification of flange and arc shield fittings to go through current transformers.
46. Same as key #360 except has flat flange seat. Use adapter 70-B-748 for 600 amp—non-magnetic adapter required for 1000 or 1200 amp.
47. Bushing key #362, 1200 amp may replace bushings key #360, 600 amp.
48. Has gauge glass.
49. Bushing key #365, 1200 amp, may replace bushing key #361, 600 amp.
50. Bushing key #370, 1200 amp, may replace bushing key #363, 400 amp.
51. Bushing key #367, 1200 amp, may replace bushing key #366, 400 amp.
52. Replacement bushing requires ring dwg 6-A-8872, item 16, for flat seat.
53. S#596933 has 600 amp rating. S#571262 has 1200 amp rating.
54. Bushing key #703 (1000 amp) may replace bushing key #701 (400 amp).
55. Normal CB rating—600 amp with cable reinforcements through tube, 1200 amp. Emergency replacement by bushings key #704 with their own arc shields and currents up to 600 amp can be made.
56. S#596934, key #260, has 600 amp rating; S#520109, key #262, has 1200 amp rating.
57. Bushing key #732, 1200 amp, can replace bushings key #731, 600 amp.
58. S#949163 has 1 layer tap; S#949164 and 1151962 have 2 layer tap.
59. S#841623 has 1 layer tap; S#841624 has 2 layer tap.
60. A new drawing replaces dwg 383626 for 34.5 kv service.
61. This bushing may be replaced by dwg 4-B-6060 where the current does not exceed 400 amps. It may be necessary to raise the oil level 2". An adapter may be required to raise the bushing if clearance at bottom end is close.
62. An adapter may be required when dwg 298260 or 623429 is replaced by dwg 2-B-2269 or 4-B-6061 because the latter is  $2\frac{3}{8}$ " longer. Also, the old bushing may have an angle flange; dwg 2-B-2269 or 4-B-6061 has a 90° flange.
63. These bushings have a special cap construction, similar to, but not identical with that described for type "K" bushings on page 17.
64. Replacement bushing drawing number will depend on design of transformer and clearances available. Refer to the factory, giving S.O., S#, or serial number of transformer.
65. Increase in oil level from 1" to 4" may be necessary with replacement bushing.

**part 5****section b: notes referring to tabulation**

66. Bushing dwg 614063 has been made both with a solid stud lead and a hollow lead for draw-through cable.
67. This is a 300/600 amp C.T. bushing which may be used as key #651 in transformers only. Central tube is larger than standard for key #651.
68. Same as key #243, except flange has slots for 4 bolts instead of three.
69. Special construction, with Micarta tube over lower part of flange.
70. This bushing for use in Inerteen transformers. Bushings for Inerteen transformers may be used on oil insulated transformers, but bushings for oil insulated transformers must not be used on Inerteen transformers.
71. This bushing is made for horizontal mounting.
72. This bushing has a detachable flange, with  $3\frac{7}{8}$ " dia bolt circle for four  $\frac{5}{16}$ " dia bolts. It may also be used with a flange and cover mounting for  $4\frac{3}{4}$ " dia B.C., four  $\frac{3}{8}$ " dia bolts.
73. Some breakers which have arc shield fittings which are clamped over condenser have current transformers of too small an I.D. to take the screwed type fittings and all bushings of this key no. may not fit.
74. Dwg 340909 has 7.5 kv, 1000 amp rating.
75. The replacement bushing differs in length outside apparatus from the original bushing.
76. Key #603, 1200 amp, can be used to replace key #604, 600 amp, S#595750, dwg 680620, S#588928, dwg 680479, are key #603, and S#595751, dwg 680620 and S#588928, dwg 680479 are key #604.
77. Has earliest type seal where packing nut of stuffing box was screwed to stud. Recommendations same as for type "C".
78. Normal CB current rating = 600 amp. With cable reinforcement—1200 amp.
79. Bushing key #714 can replace bushing key #706 for  $16\frac{1}{4}$ " B.C. only.
80. Dwg 70-A-522 cannot be used on circuit breakers.
81. Has external Inerteen reservoir.
82. Not adapted for use with circuit breaker arc shields.
83. Key #666, 1200 amp or key #665, 600 amp, can be used to replace key #664. Key #664 cannot be used on circuit breakers as not adapted for arc shields.
84. Key #717, 1200 amp or key #715, 800 amp can be used to replace key #714. Key #714 cannot be used in circuit breakers as not adapted for arc shields.
85. Key #755, 1200 amp or key #756, 1200 amp can be used to replace key #754. Key #754 cannot be used for circuit breakers as not adapted for arc shields.
86. Key #805, 1200 amp or key #806, 800 amp can be used to replace key #804. Key #804 cannot be used on circuit breakers as not adapted for arc shields.
87. Key #856, 1200 amp or key #857, 800 amp can be used to replace key #854. Key #854 cannot be used on circuit breakers as not adapted for arc shields.
88. The original breaker current transformer and transformer case should be checked for fit with the replacement bushing.
89. Use an adapter when the old bushing has an angle flange.
90. See dwg 12-A-3636 for revamping with spun cap.
91. See dwg 12-A-3637 for revamping with spun cap.
92. See dwg 12-A-3345 for revamping with spun cap.
93. See dwg 12-A-4560 for revamping with spun cap.
94. See dwg 14-A-1675 for revamping with spun cap.
95. See dwg 15-A-1193 for revamping with spun cap.
96. The bushing has a beveled flange seat and tapered lower end.
97. The replacement bushing requires a lead extension and static shield.
98. Spares or replacements may be type "O".
99. When the type "O" is used as a replacement on transformers bought before 1944 it is necessary to check against mechanical interference between barriers and lower end of the bushing.
100. Has draw-through lead.
101. Special for Consolidated Gas Electric Light & Power Company.
102. This bushing has cap and bell connector combined.
103. With lead extension, this bushing can be used to replace bushings key #731.

104. With lead extension, this bushing can be used to replace bushings key #732.
105. Special design.
106. Has lead straight through cap, without switch jaw.
107. Replacement bushing requires lead extension and additional static shield.
108. For circuit breakers only.
109. Bushing has magnetic oil gauge.
110. Dwg 7-A-7004Gr3 for breakers without "De-ion" Grids.  
Dwg 7-A-7004Gr4 for breakers with "De-ion" Grids.
111. Group number, as well as drawing number must be specified to identify original bushing. Special gaps were supplied with original bushing; these gaps will not fit the replacement bushing. Special gaps for the replacement bushing should be ordered separately, if desired.
112. Inner end of this bushing must be entirely under oil (or Inerteen).
113. This bushing is supplied with a special flange designed to obtain uniform, limited gasket compression. Construction is described in instruction leaflet 3172.
114. Special flange construction. Bushing flange is welded to transformer cover.
115. Dwg 4-B-4509 has central lead threaded for 1 1/4-14 threads at top and bottom; otherwise it is the same as key #419.
116. This bushing may be mounted horizontally or vertically.
117. Has shield layer for power factor test.
118. Has sight oil level indicator.
119. Used only as a roof bushing on transformer-switchgear housing.
120. Bushing has greater internal diameter than A.S.A. standard bushing of same key number. Check clearance to metal porcelain support at the bottom end of bushing.
121. For indoor use only.
122. Replacement bushing meets all A.S.A. standard dimensions and characteristics.
123. Replacement bushing has A.S.A. standard threading on terminals.
124. Replacement bushing is a 15 kv bushing.
125. A cable adapter is required with the replacement bushing.
126. These bushings are concentric lead bushings.
127. These bushings for 45° mounting and require a special boss.
128. These bushings have insulated stud for power factor testing.
129. These bushings have pressure gauges on flange.
130. These bushings for metering outfits.
131. These bushings for 35° mounting.
132. Replacement bushing has special gaps.
133. Replacement bushing requires new top and bottom terminals.
134. These bushings are special for Detroit Edison with rolled on flange.
135. These bushings have smooth studs both ends.
136. These bushings are special for Detroit Edison with grooved studs.
137. These bushings have provisions for protective link.
138. Bushing has 1 1/2-12 thread at top.
139. Extra mechanical strength bushing for high kva interruption.
140. Bushing has extra creepage.
