supersedes descriptive bulletin 41-130 dated August, 1957  
mailed to: E/320/DB; D65-5A; C/371/DB; C29-5B

**CR line****operation****selection of characteristic time curve**

When the generation is fixed at a constant value and fault current variation is primarily due to the location of the fault along a line, the selection of a relay with a more inverse time characteristic is desirable to obtain selective coordination with adjacent relays.

**settings****a. tap range****taps available**

0.2	0.6	0.8	1.0	1.5	2.0	2.5
2	2.5	3	3.5	4	5	6
4	5	6	7	8	10	12

The current range selected depends upon the fault current available at the protected line, as determined by a system study. The lower tap range, 0.5-2.5 amperes, is usually applied for ground fault protection since phase faults result in higher fault currents requiring the 2.6 or 4-12 amp range.

**example of settings for a loop protection**

Fig. 8 illustrates a loop system with one generating station equipped with overcurrent relays and four substations equipped with directional overcurrent relays. Arrows indicate the direction overcurrent must flow to trip the relays, and the time values represent the operating time of the relays as determined by the time dial position.

When the generation fluctuates within large limits such as day-time peak and night time low, the tripping time of a relay with an inverse characteristic becomes too dependent on the magnitude of the fault current to permit a smooth coordination so that the relay with definite minimum time is the preferred choice.

**b. time dial**

The effect of the time dial adjustment is shown on the curves, fig. 33-39. Time dial settings determine the operating time of the relay. See page 14.

**c. spring adjuster**

By rotation of the spring adjuster it is possible to obtain continuous pick-up current values between the tap settings, thus permitting a very selective time coordination.

Considering a fault at M, current will flow to the fault from substations B and C. The 0.35 second relay will trip at substation C and the 0.85 second relay will trip at substation B. While the same fault current flows through the 0.6 second relay at station D, and the 0.85 second relay at station E, the 0.35 second relay at station C will operate and close its contacts before the 0.6 relay at D or the 0.85 relay at E can trip.

## 1 instantaneous overcurrent unit (I)

This cylinder-design unit is similar in construction to the directional unit except that it has one circuit closing contact. Each pair of pole windings is energized by ground current from the operating circuit. A capacitor is series-connected with one pair of pole windings to obtain the desired time-phase relationship between the current in the two pairs of coils, in order to develop the necessary rotational torque. As shown in figures 26 and 27, one of the directional unit contacts (D) is connected across one pair of pole windings of the instantaneous overcurrent unit. This contact shunts the operating current around the pole windings, preventing the instantaneous overcurrent unit from developing rotational torque. However, when the directional unit picks up under fault conditions, the short on the instantaneous overcurrent unit coils is removed, allowing the instantaneous overcurrent unit to commence closing its contact almost simultaneously with the directional unit . . . thus providing high speed operation.

A saturating transformer is used to feed the instantaneous overcurrent unit. This transformer limits the energy applied to the unit at high current values and reduces the burden on the current transformer. The primary winding of the saturating transformer has taps connected to a tap block to facilitate changing the current pickup values of the unit. Tap value current is the minimum current required to just close the relay contacts. Pickup in between tap values can be obtained by varying the position of the spiral spring adjuster. This tapped transformer arrangement supplies the same amount of energy to the overcurrent unit for any tap setting at a given multiple of tap current. Thus, the unit has a constant burden level throughout its entire range.

A non-linear resistor (varistor) is connected across the secondary winding of the transformer and overcurrent unit coils to reduce the voltage peaks applied to the phase shifting capacitor and the overcurrent unit.

## 2 current polarized directional unit (D)

## 3 voltage polarized directional unit (D)

The directional unit is a product type induction cylinder which operates as a result of the interaction of polarizing and operating current flux. The moving element consists of a spiral spring, a contact-carrying arm and an aluminum cylinder which rotates in the air gap formed by the electromagnet and the magnetic core. The unit is free of vibration at heavy currents. It provides fast, trouble free reliable operation and requires no setting. The electro-magnet has two series connected polarizing coils and two series-connected operating coils mounted opposite each other. The interaction of the fluxes generated results in rotation of the cylinder. At 20 amperes operating current with 120 volts, 60 cycles applied, the operating time of the directional unit is approximately 10 milliseconds.

## 4 time-overcurrent unit

The types CO-5, CO-6, CO-7, CO-8, and CO-9 electromagnets consist of an "E" shaped laminated magnetic core which has a main tapped coil on the center leg of the "E" structure. The flux produced by this main coil divides and returns through the two outer legs. A shading coil located on the left leg of the electromagnet shifts the flux in that leg out of phase with respect to the flux in the right leg. The out-of-phase flux thus produced in the air gap of the electromagnet interacts with the main coil flux to create contact closing torque on the induction disc.

The CO-2 and CO-11 electromagnets are similar in construction, except that they have shading coils on both outer legs of the "E" shaped electromagnet. Disc rotation is opposed by the spiral spring which resets the moving contact to its initial position when applied current is below the tap value setting.

## 5 Indicating Contactor Switch (ICS)

Two are used (see page 3 for description), one designated ICS/I to indicate completion of the trip circuit due to closing of the instantaneous (I) unit contacts; the other ICS/T which operates when the time-overcurrent (CO) unit operates.

## IR line construction

### Indicating Instantaneous Trip (IIT)

when used with CR phase relays (see figure 9 )

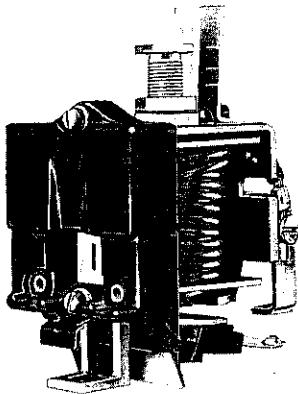

fig. 25

The Indicating Instantaneous Trip unit is similar in construction to the ICS unit except that it is a-c operated and is adjustable over a range of 1 to 4 times minimum pickup. Variable pickup is provided by the core screw adjustment on the top of the unit.

Each unit has a calibrated scale on which are marked four divisional points of the unit's pickup range (such as 10-20-30-40 for the 10-40 amp unit). A calibrated scribe mark on the scale plate indicates the exact position of these current pickup values.

The IIT unit has an operating accuracy of  $\pm 10$  percent of setting. Ratio of dropout to pickup varies from 65 percent at minimum setting to 90 percent at maximum setting.

### relay settings

The instantaneous and time-overcurrent units require setting, whereas the directional unit does not.

On both overcurrent units, the tap selected determines the minimum pickup or contact-closing current of the unit. Selective time dial settings on the time-overcurrent unit can be determined by referring to the time current curves on pages 14 and 15.

Stationary contacts are adjusted as noted on page 3.

The Indicating Contactor Switch (ICS) tap is selected as stated on page 3.

① Thermal capacities for short times other than one second may be calculated on the basis of time being inversely proportional to the square of the current. For instance, on the 0.5/2.5 amp range, one second rating being 88 amps, the half-second rating x would be obtained from:

$$\frac{1}{0.5} = \frac{x^2}{88^2} \times \sqrt{15488} \approx 124 \text{ amps}$$

② Degrees current lags voltage at tap value current.

③ Voltages taken with Rectox type voltmeter.
